 A Fansler Minneapolis Vice Chairman Ernest H Gauthier Baltimore
 Secretary Henry L Bockus 250 South 18th Street Philadelphia

RADIOLOGY—Chairman John W Pierson Baltimore Vice Chair
 man Bernard H Nichols Cleveland Secretary John T Murphy 4-1
 Michigan Street Toledo Ohio

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1934

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "B," Bureau of Investigation, "E," Editorial, "C," Correspondence, "ML," Medical Economics. "ab," abstract, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2292

THE RÔLE OF PHARMACOLOGY IN THE DEVELOPMENT OF IDEAL ANESTHESIA

C D LEAKE, PH D

SAN FRANCISCO

Since no drug is quite ideal for its purpose stimulus exists for commercial as well as scientific efforts to develop better drugs than any now in use for a particular clinical effect. Scientifically, such an effort is usually based on some phase of what may be called biochemorphology,¹ i e, the relation between chemical constitution and biologic action. A chemist, after considering, for instance, the biochemorphic aspects of hypnotics synthesizes a new substance which is found to have hypnotic action. Commercially there now exists a strong temptation to introduce the new agent clinically without furnishing physicians sufficient comparative scientific data to enable them to judge whether or not it has advantages recommending it over hypnotics already in common use. One would be naive indeed to believe that the pharmaceutical concern developing the new hypnotic could give unbiased judgment on this point. But it is thus that the hopeful good humor of physicians is too often exploited with unnecessary harm or expense to their patients.

Four years ago, before the Portland session of the American Medical Association, I tried to outline in a general way the position of pharmacology in the appraisal of drugs suggested for general use in medicine.² It was pointed out that clinical trial of a new chemical should be made only after disinterested pharmacologic study has estimated in comparison with related agents (a) its possible harmful effects, (b) its type or mode of action and (c) the reasonableness of its replacing existing drugs in application to human beings. It was further indicated that the new agent should not be offered for general use to physicians until favorable reports on it had been published from reliable chemical, pharmacologic and clinical sources. Pharmacologic data are more readily accepted from university laboratories than from commercial labora-

tories, and clinical information is usually relied on when it comes from a university or independent research hospital. Physicians might place greater confidence in commercial concerns if they would cooperate with such institutions rather than supplant them with their own. While it is to be hoped that Sir Henry Dale's pious good wishes for American pharmaceutical houses may come true,³ past experience indicates that American physicians must support more fully the judgment of the Council on Pharmacy and Chemistry of the American Medical Association and insist more strongly on adequate and reliable pharmacologic and clinical data in connection with new drugs if they are to free themselves from exploitation. One need only think of the current situation in local anesthesia and preanesthetic medication to realize the significance of these remarks. It is yet to be satisfactorily demonstrated, not only pharmacologically and clinically but also from the standpoint of expense, that for infiltration and spinal anesthesia or nerve block a better local anesthetic is available than procaine, that any of the many modifications of barbitol surpass it for ordinary preanesthetic hypnosis⁴ or that tribrom-ethanol ("Avertin") is better than paraldehyde for rectal narcosis.⁵

RATIO OF TOXICITY TO EFFICIENCY

In the pharmacologic evaluation of new chemicals for various uses in anesthesia as elsewhere, the essential proposition is the critical quantitative estimation of the ratio of the toxicity of the substance to its efficiency in comparison with related agents. Both the toxicity and the efficiency must be thoroughly investigated. It is not enough to estimate an average lethal dose (M L D). This gives no information regarding the minimal dosage, either single or total cumulative, at which harmful effects may be encountered in the susceptible organism, which in the case of the human being is just the one to protect. For some drugs the toxic dose range is wider than for others because there may be a greater individual variation in response to it.⁶ The physician should have this full information. If the toxic dose range overlaps the effective dose range, the drug is not a safe one. In appraising a series of drugs giving a satisfactorily intense and prolonged effect, the one that has the greatest margin of safety between the effective dose range and the toxic dose range will be best in general. Too seldom are full data on this essential matter in anesthesia given to physicians.

Some of these propositions may be illustrated to advantage in connection with problems of current

² Read before the Section on Miscellaneous Topics Sessions on Anesthesia at the Eighty Fourth Annual Session of the American Medical Association Milwaukee June 15 1933.

³ The adjective biochemorphic has been coined to connote that pertaining to the relationship between chemical constitution (including physical properties) and pharmacologic (physiologic or biologic) action. Such a term is badly needed especially when the restricted term chemotherapy (Ehrlich) is becoming loosely employed to cover this whole field (e g Dyson G M The Chemistry of Chemotherapy London 1928). The noun indicating the study of the relationship between chemical constitution and biologic activity would be biochemorphology. The literal meaning of the term knowledge of living chemical structure really implies the fundamental objective of investigations on the relationships between chemical constitution and biologic activity so that there is no essential conflict with its technical meaning.

interest in anesthesia. For general inhalation anesthesia, although a number of substances are commonly used, not one is ideal. Partly by accident and partly by deliberation,⁸ the anesthetic properties of the unsaturated hydrocarbon ethylene ($\text{CH}_2=\text{CH}_2$) were rediscovered in 1922, although they were known to Richardson fifty years before.⁹ This revived interest in the search for better general anesthetics since ethylene, in spite of its explosibility, was found to have many physiologic advantages over its competitors.¹⁰ It was found that further unsaturation as in acetylene ($\text{CH}\equiv\text{CH}$), or increasing the number of carbon atoms, as in propylene ($\text{CH}_3-\text{CH}=\text{CH}_2$), does not seem to improve the anesthetic qualities but may introduce undesirable ones. The careful studies of Prof. V. E. Henderson and his associates on the cyclohydrocarbons, however, are most promising and have led to

the demonstration of cyclopropane $\begin{array}{c} \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{CH} \quad \text{CH} \\ \diagdown \quad \diagup \\ \text{CH}_2 \end{array}$ is a

relatively nontoxic and powerful inhalation anesthetic worthy of clinical trial.¹¹ Rather than discuss this I hope I may be pardoned for the seeming egotism of using as an illustration work with which I am more directly familiar.

DIVINYL OXIDE AND VINYL CHLORIDE

A consideration of the biotransformation aspects of general anesthetics led to the prediction that a compound incorporating the structural characteristics of ether ($\text{CH}_3-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_3$) and ethylene ($\text{CH}_2=\text{CH}_2$) would be a general anesthetic and further that this unsaturated ether ($\text{CH}_2=\text{CH}-\text{O}-\text{CH}=\text{CH}_2$, divinyl oxide) would be better than any unsaturated ether with a greater number of carbon atoms in the side chains. When this prediction was made, divinyl oxide, although theoretically known to chemists did not exist. When I requested this specific compound with other unsaturated ethers from Prof. Lauder Jones of Princeton University, his associates, Drs. Randolph Major and W. T. Ruigh, sent me an impure sample which was found, however, to have the properties predicted of it.¹² Later Drs. Major and Ruigh¹³ became associated with the Laboratory of Pure Research of Merck & Co. and prepared for the first time pure divinyl oxide, which they were kind enough to furnish in amounts large enough for pharmacologic study and later for clinical trial when its advantages had been demonstrated.¹⁴ Pure divinyl oxide, although explosive like ether and ethylene, is more powerful and rapid in its anesthetic action. It is more volatile than ether (boiling point

28.3 C) and less irritating locally, and its general physiologic effects are less severe. It has no significant pathologic effect when administered without anoxemia. Its minimal certain anesthetic concentration, like ether, is about one-third its minimal toxic concentration when allowed to act for ten minutes, but greater circulatory reserve remains when respiration fails. Recovery is more prompt than from ether or ethylene and less attended with nausea or other complications. A great practical advantage revealed by animal experimentation is that abdominal relaxation, without intercostal muscular paralysis may more easily be obtained with divinyl oxide than with other common general anesthetics. Following our pharmacologic studies, Gelfan and Bell¹⁵ of the University of Alberta demonstrated its safety in anesthetic concentrations for man. At its first surgical use with Dr. Dorothy Wood as anesthetist at the University of California Hospital, San Francisco, in an operation on an obese patient for removal of the gallbladder its practical advantages were clearly evident. These have now been independently confirmed.¹⁶

But divinyl oxide is not of course an ideal inhalation anesthetic. In addition to its explosibility and probable expense, it may polymerize or decompose with the appearance of such dangerous irritants as formaldehyde and formic acid. Difficulty with such impurities has already been experienced.¹⁷ But so far results justify the hope that similar biotransformation studies may lead more closely to an ideal general anesthetic.

Further steps in this direction are being taken in our laboratory. Dr. S. A. Peoples is investigating the anesthetic properties of the halogenated unsaturated hydrocarbons. These were suggested by the fact that the union of a halogen with an unsaturated carbon atom is more stable than otherwise, so that such compounds might not be expected to decompose in the body causing untoward effects, as seems to be the case with saturated halogenated hydrocarbons.¹⁸ Vinyl chloride ($\text{CH}_2=\text{CHCl}$) which may most appropriately be compared to ethyl chloride ($\text{CH}_3-\text{CH}_2\text{Cl}$), is a gas (boiling point -13.9°C) heavier than air and with an ethereal odor. Its narcotic action has already been noted.¹⁹ Dr. Peoples²⁰ found that although it is not quite as powerfully anesthetic as ethyl chloride, it has a wider margin of safety between its anesthetic range and its toxic range. It is very rapid in its action and recovery from it is prompt with no apparent untoward effects, even after prolonged anesthetization. It is, of course, much more powerful than ethylene as a general anesthetic, and significantly it is not explosive. It is also very cheap. The chlorine in it is split off only with difficulty, so that physiologically it seems relatively free from many of the untoward effects of ethyl chloride. It remains for further pharmacologic study to indicate whether or not it is worthy of use in human beings. Dr. Peoples is also studying higher halogenated unsaturated hydrocarbons, such as β -bromopropylene ($\text{CH}_3-\text{CBr}=\text{CH}_2$), which are nonexplosive and powerful anesthetics.

IMPORTANCE OF TECHNIC

Biochemorphic studies, such as those of Prof V E Henderson's on the cyclohydrocarbons and those on unsaturated hydrocarbons, illustrate the role pharmacology may play in the development of ideal inhalation anesthetics. Technique is another phase of the pharmacologic evaluation of anesthetics which may aid in achieving ideal anesthesia. In our studies on dimethyl oxide we had occasion to examine critically various methods of administering inhalation agents. No method in our opinion is as sound physiologically as reflected in the anesthetic and postanesthetic condition of the organism as the Waters²¹ carbon dioxide filtration technique. In our experimental work we found that such complicating factors in general anesthesia as water or heat loss from the lungs, asphyxiation, anoxemia and carbon dioxide accumulation can be reduced to a minimum by this method. Furthermore, it minimizes loss or waste of anesthetic and permits very accurate control. In this study we were impressed again with the importance of anoxemia as a factor in the deleterious physiologic effects of a general anesthetic. These considerations are more significant clinically when human life is at stake than experimentally. Pharmacology may thus be helpful in evaluating anesthetic technique. This is now so complex involving so many difficult physiologic and pharmacologic propositions, that it must be obvious that anesthesia is a medical specialty worthy of the best attention of able physicians, and that it can no longer be entrusted to individuals with inadequate medical training without denying surgical patients the skill they deserve.

CHEMICAL ADJUNCTS TO ANESTHESIA

A great variety of chemical adjuncts to anesthesia have been proposed for (a) preanesthetic hypnosis, (b) regulation of metabolism preoperatively, (c) aid in the induction, maintenance and prompt recovery from direct anesthesia, (d) relief of postanesthetic nausea, and (e) postoperative analgesia. Reference to pharmacology in this overgrown field would greatly help in approaching more ideal conditions than those now existing, especially regarding preanesthetic hypnotics. It should be clinically obvious that routine preanesthetic medication or use of chemical adjuncts to anesthesia is not in the best interests of the patient. Each patient should be individually considered with regard to the chemical to be used, if necessary at all, and its dosage and mode of administration. Axiomatic though this may be, it is usually honored in the breach in anesthesia.

Pharmacologic evidence indicates that much traditional rubbish in common beliefs regarding morphine, atropine and scopolamine (hyoscine) might be removed with advantage to anesthetic practice. The objections to morphine are central nervous system stimulation outlasting the obvious depression, tendency to cause constipation, tendency to disturb carbohydrate and fat metabolism, depression of respiration and interference with rapidity of absorption and excretion of a volatile anesthetic.²² Nevertheless, it remains the best preanesthetic hypnotic and postoperative analgesic when traumatic pain is present. Codeine is preferable if the

traumatic pain is slight. It is to be hoped that the thorough biochemorphic studies of Small and Eddy may lead to the discovery of an ideal agent in this regard.²³ In congestive pain, amidopyrine or a similar acting antipyretic which seems to restore fluid from tissues to blood²⁴ may be recommended as a substitute. Little rational evidence exists that opium or a mixture of its alkaloids free from nonalkaloidal material ("pantopon") has any advantage over morphine as a preanesthetic hypnotic; indeed the evidence is otherwise.²⁵ Atropine has rational indications when chloroform or ethyl chloride are to be used or when an embarrassing mucous or salivary flow is expected. Otherwise it has little merit in anesthesia, its relaxation of the intestine probably contributing to the frequent postoperative stasis. What critical pharmacologic or chemical information is available regarding scopolamine fails to justify its use in anesthesia.²⁶ Since it is chemically related to atropine, it may be expected to have actions and disadvantages similar to the latter.

Current interest in preanesthetic hypnotics is focused on the barbiturates, to the unfortunate neglect of many other equally promising chemical types. On pharmacologic evidence from normal human beings, barbital by mouth may be recommended as a suitable preanesthetic hypnotic if no pain is present.²⁷ Although commercial rivalry has produced an amazing number of modifications of barbital satisfactory evidence is still lacking to show the undoubted superiority of any of them over barbital. The biochemopharmacology of this group of drugs has been well reviewed by Shonle.²⁸ As an example of gross commercial exploitation in this field, combinations of barbiturates in fixed proportions with amidopyrine ("allonal," "cibalgin," "pyrammal") may be mentioned. In spite of direct pharmacologic evidence of the danger of such mixtures,²⁹ since the analgesic component is excreted more rapidly than the hypnotic, so that cumulative barbital poisoning is possible on repeated administration, they remain "successful." Similarly, the "success" of tribrom-ethanol as a 'basal anesthetic' is chiefly commercial, pharmacologic and clinical evidence failing as yet to indicate that it is any better than paraldehyde by rectum.³⁰

My destructive criticism should not lead to a loss of hope that hypnotics more satisfactory than those commonly used now may not be found. The principles of biochemopharmacology may be expected to advance our knowledge to this end if they may be patiently and steadfastly pursued without the pressure of business expediency. Dr P K Knoefel³⁰ in our laboratory has made some interesting studies on the paraldehyde series which may be of practical significance.

Many hypnotics of different chemical types, which may be used as basal narcotics, seem to inhibit the gen-

cial hyperactivity of the sympathetic nervous system caused by ether, chloroform and other volatile anesthetics. Knoefel has suggested that their use therefore may be an important factor in counteracting supranal exhaustion and anesthetic shock.³⁰ Pharmacologic study should indicate what hypnotics are best suited for this purpose.

In many other cases in which chemical adjuncts to anesthesia are used as for respiratory or circulatory stimulation disinterested critical pharmacologic evidence of the value of new drugs should be demanded before clinical trial is undertaken. The advances made by biochemorphic studies in the epinephrine series³¹ justify the hope that their continuation may lead to more ideal agents in this group for adjunctive use in anesthesia than any now available.

LOCAL ANESTHETICS

As an example of sound critical pharmacologic evaluation along the lines I have suggested the work of Sollmann³² and of Schmitz and Loevenhart³³ in the procaine series of local anesthetics is outstanding. Here is a field in which biochemorphology has been used to produce such an abundant harvest that its pharmacologic evaluation, except in scattered instances, has scarcely begun.³⁴ Pending this necessary comparative pharmacologic appraisal, clinicians should be very cautious in using new local anesthetics on their patients. It is in this field especially that the ratio of toxicity to efficiency in comparison with related agents or with standard local anesthetics is most important. Fortunately, these comparative ratios may be accurately estimated by proper pharmacologic methods. Clinicians should insist that data of this sort be plainly and fully presented so that they may be the ones to judge of the worthiness of new substances for clinical uses. For surface (mucous membrane) anesthesia it is desirable that thorough study be made of local anesthetics in order to find such satisfactory substitutes for cocaine that there will not longer be any hesitancy in discarding completely this dangerous habit former. For infiltration or subarachnoid anesthesia or nerve block, procaine will be hard to surpass because of its unusually wide margin of safety between its effective and toxic doses.

In the quinine series there is the possibility that biochemorphic considerations may aid in the finding of relatively safe and efficient local anesthetics with prolonged action. Nupercaine is by no means ideal in this regard, but its development indicates the hope.³⁵ There is also the hope that prolongation of action may be achieved in the relatively safer procaine series by biochemorphic studies. But this desideratum may be attained by other methods suggested by pharmacologic observations. Absorption may be delayed by causing local vasoconstriction, as is commonly done by adding epinephrine to a local anesthetic solution. But this

increases the toxicity of the local anesthetic, and substituting ampules of pitressin for epinephrine gives no advantage.³⁶ Biochemorphic considerations have suggested incorporating vasoconstricting and local anesthetic properties in a single chemical substance, and the recent synthesis of many such agents³⁷ offers the hope of advance in this direction toward more ideal local anesthesia. Some compounds being studied in our laboratory by Knoefel and Alles seem very promising.

Reduction of absorption by local vasoconstriction is also an important factor in minimizing systemic poisoning by local anesthetics. But the discovery of the prophylaxis of systemic local anesthetic toxicity by means of the barbitals and certain other hypnotics³⁸ is a practical pharmacologic contribution of greater significance in the development of ideal anesthesia, since it may be used to relieve the patient's fear and excitement as well as to protect against untoward reactions. The possibility of incorporating central nervous system depressant action with local anesthetic action in the same chemical has been proposed by Dr. Knoefel on biochemorphic grounds. His studies indicate definite hope in this direction.³⁹

SUMMARY

In the development of ideal anesthesia, pharmacology must play a major role particularly in the critical appraisal of the relative merits of new chemicals proposed for use in anesthesia. Significant advance may follow studies on the relation between chemical constitution and biologic action (biochemorphology). Such a possibility is already promised for inhalation anesthesia by observations on the cyclohydrocarbons, unsaturated ethers and hydrogenated unsaturated hydrocarbons, and especially for preanesthetic hypnotics and local anesthetics by a variety of chemical types. Unfortunately, commercial considerations have largely dominated this field so that proper pharmacologic data on new drugs, especially relating to toxicity and efficiency in comparison with related or commonly used agents, have not usually been furnished physicians to enable them to judge whether or not the new drugs are worthy of clinical use. Such data may advantageously be secured by cooperation with university medical laboratories. Loevenhart proposed a cooperative therapeutic institute for obtaining data of this sort under ideal conditions but unfortunately commercial houses were unwilling to establish and support it.⁴⁰

ABSTRACT OF DISCUSSION

DR. M. H. SLEEVERS, Madison, Wis.: When the time comes for the clinical trial of a new drug even after extensive pharmacologic investigation with favorable results, one must proceed as cautiously as if one had little or no knowledge of the drug, because additional action which did not manifest itself in the lower animals may preclude its clinical use. A capable anesthetist, who has been in the foreground in the clinical trial of newer anesthetic agents, recently stated that he will not attempt to evaluate any new drug until it has had an extensive clinical application.

CEREBRAL CYSTS

WINCHELL MCK CRAIG, M.D.
AND
JAMES W. KERNOHAN, M.D.
ROCHESTER, MINN.

The clinical syndromes produced by intracranial lesions follow fairly definite lines of progression, and may indicate the underlying pathologic changes. However, it is reasonable to assume that a definite pathologic diagnosis can be made only at operation or necropsy. General and neurologic examinations may indicate whether the lesion is primary or secondary, inflammatory or neoplastic, and encephalography or ventriculography may be necessary to assist in localization.

When the lesion has been localized and found suitable for operation, it is important to determine whether it is cortical or subcortical, cystic or solid and neoplastic or non-neoplastic. Because of the difficulty in distinguishing between cerebral cysts at the time of operation, we have reviewed the various types for the purpose of comparison. Between 10 and 15 per cent of the surgical conditions of the brain were found to be cystic. This particular group of conditions involving the cerebral hemispheres has been considered with regard to etiology, and has been divided into congenital, inflammatory, traumatic, parasitic and neoplastic types.

Congenital cysts may be subdivided into porencephalic, epidermoid and simple. Porencephalic cysts either communicate with the subarachnoid space and the ventricle, or extend so deeply into the substance of the brain that they cause distortion of the ventricular outline. The walls of epidermoid cysts are lined with epithelium in which there are few glandular structures, and the contents are not fluid, but caseous. Among the cysts encountered at operation are subcortical cavities containing clear fluid, the walls of which are smooth and glistening and in which there is no evidence of neoplasm or inflammation. In the absence of a history of trauma or evidence of inflammation these have been designated congenital simple cysts.

Inflammatory cysts are rare and consist either of collections of fluid in the chronically inflamed pia-arachnoid space, or subcortical collections of fluid associated with chronic encephalitis. There is usually little evidence that these cavities are the end-result of the liquefaction and absorption of a previous abscess.

Traumatic cysts may be divided into subdural hematomas, calcified, and simple cysts. It is questionable whether subdural hematomas should be included in this group because they occur between the dura mater and the cortex of the cerebrum. Calcified cysts are frequently the result of a subcortical hematoma, and are encountered at an age when spontaneous hemorrhages are not likely to occur. In addition to the congenital simple cysts, smooth-walled cysts have been encountered following a definite history of trauma, these contain clear fluid. In the walls of these cysts there is no evidence of neoplasm.

The most common parasitic cyst encountered at operation consists of the collection of fluid due to infestation by *Echinococcus*. These cysts may be solitary and frequently contain daughter and granddaughter

cysts and may occur subcortically, or they may be attached to the meninges.

The neoplastic cyst is by far the most common type encountered at operation. It varies almost in direct proportion with the frequency with which various types of neoplasms occur in the cerebrum. Almost all types of tumors have been found associated with cysts, and the more benign and slow-growing types seem to have a greater tendency to degenerate and form cysts than the more rapidly growing ones.

Tumors of the glioma group which were found to contain cysts were spongioblastoma multiforme, ependymoma, polar spongioblastoma, oligodendroglioma, astrocytoma and gangliocytoma. Cysts also were encountered, associated with hemangio-endotheliomas and rarely with meningiomas.

A less important group of cysts encountered among elderly patients are those associated with arteriosclerosis. They are liquefied infarcts in which absorption of the debris has been completed, and which contain clear fluid. Blood pigment is often found in the walls of these cavities.

Lesions such as subdural hematoma, calcified cysts and echinococcus cysts may have demonstrable characteristics which immediately lead to a diagnosis. However, following exposure and aspiration of a subcortical cerebral cyst it is extremely difficult to identify its origin and pathologic changes. Realizing these difficulties, we are analyzing some of the more prevalent of these cerebral cysts in an effort to emphasize the outstanding characteristics.

The first case presented illustrates a congenital cyst which is an exaggeration of the condition of porencephaly or developmental absence of a portion of the cerebral hemisphere. This case has been described in detail elsewhere, however, since it is a good, even if extreme, example of this type of lesion, a brief summary is given.

REPORT OF CASES

CASE 1—Porencephaly. A girl, aged 7 months, was brought to the Mayo Clinic because of progressive enlargement of the head. The child seemed normal for the first week after birth, and then began to have generalized convulsions. Because the head had increased in size and the convulsions were increasing in severity, the right lateral ventricle was aspirated through the anterior fontanel. The procedure relieved the convulsions, and it was repeated at intervals. However, the head gradually increased in size so that at the time of examination in the clinic it measured about 50 cm in circumference, and the fontanels and sutures were open. The right side of the cranium was larger than the left. The results of neurologic examination were negative, the child moved all four extremities with equal strength, and the reflexes were slightly hyperactive. Dye was injected into the right lateral ventricle and was recovered by means of posterior cistern puncture. A ventriculogram revealed what appeared to be a markedly distended right lateral ventricle and a smaller left lateral ventricle.

When the dura was opened, clear fluid was aspirated, and with the aid of a lighted retractor, it was seen that the entire right hemisphere was absent, and only the basal ganglia were present. The falx cerebri, sella turcica and tentorium were visible, and we could see into the left lateral ventricle through the intraventricular foramina, which were very large. The choroid plexuses of the right and left lateral ventricles were removed.

Possibly this case should be in the porencephalic group of congenital cysts, which may simulate neoplasms or hydrocephalus. It is conceivable that a simple cyst could be present within the brain, caused either by inflammation or by a congenital anomaly. The classification of simple cysts would seem satisfactory

Read before the Section on Nervous and Mental Diseases at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee, June 16, 1933.

for those having smooth walls, and clear fluid, and apparently being neither neoplastic nor congenital

CASE 2—Simple cyst A man, aged 37, came to the clinic complaining of convulsions and failing vision of one year's duration. Four years before, when at work, he had suddenly lost consciousness, which lasted for twelve hours. Three months later, he had another seizure, and similar but shorter attacks occurred as frequently as four or five times a day. He occasionally fell but recovered immediately and complained of slight transitory confusion during which he suffered from propulsion or retropulsion. At the time of his first attack he noticed that he could not see objects on the right side. There were never any headaches or vomiting, but there was a marked change in personality, this led to the loss of his position and friends, and he had little interest in his surroundings.

General physical examination and laboratory studies gave negative results. Roentgenograms of the head revealed increased intracranial pressure. Anisotropia of the right eye was complete, and vision in the left eye was diminished. The left field of vision showed marked concentric contraction, with an enlarged blind spot and no color vision. The pupils were slightly irregular, the left was larger than the right. There were bilateral secondary optic atrophy and residual edema of

Fig. 1 (case 4)—Lateral view of a calcified cyst in the left frontal lobe

the disks, 1 diopter in the right eye and 2 diopters in the left. Neurologic examination revealed an increase of the Achilles reflex on the right, and a reduction on the left. A ventriculogram localized the lesion in the right frontal lobe.

At operation a subcortical cyst was found when the mid-frontal convolution was incised. The cyst measured 10 cm in diameter and contained 240 cc of clear fluid. The walls were smooth and fibrous, and neither gross nor microscopic evidence of tumor could be found. The cyst was connected with the anterior horn of the right lateral ventricle to secure permanent drainage.

The patient recovered uneventfully. His mentality was greatly improved. No change could be discovered in the right eye, but there was marked improvement of vision in the left. Two years after operation, he could read fine print with correction, and improvement in his general condition had been progressive. He had returned to work and was supporting his family.

This simple cyst became sufficiently large to create slowly progressive increased intracranial pressure. The papilledema and optic atrophy, as well as the roentgenologic evidence of increased pressure, suggested a long course. The satisfactory response to operation with ultimate recovery indicated that little of the surrounding cerebral tissue had been destroyed.

In the third case the cyst was believed to be of traumatic origin, and yet this could not be determined prior to operation, because neoplasms may have a similar history of trauma.

CASE 3—Traumatic cyst A boy, aged 10 years, was brought to the clinic because of convulsions. Three years before, he had been thrown from a merry-go-round, striking the left side of his face and head, this had not been associated with loss of consciousness or ill effects. A year later he had a syncopal attack which was followed by a sensation of numbness of the right thumb associated with temporary contraction of the hand and arm. Four weeks later, he had a grand mal seizure which was followed at irregular intervals from a few hours to several months, by jacksonian convulsions, which began in the right hand and sometimes involved the leg but were not associated with loss of consciousness. Occasionally the right side of the face was involved. For six months prior to his examination at the clinic, administration of phenobarbital had diminished the number and intensity of his convulsive seizures.

General and neurologic examinations, including laboratory tests, and ophthalmologic examination gave negative results. A diagnosis was made of a lesion of the brain involving the left motor area.

At operation a cyst measuring 6 cm in diameter was found in the middle and inferior frontal convolutions on the left side. It was subcortical, and the vessels which are normally on the cortex were in the exposed wall of the cyst. Three of these vessels were ligated, the roof of the cyst was incised, and the contents consisting of clear fluid were aspirated. The lining was white and fibrous, and there was no mural tumor.

The postoperative condition of the patient was satisfactory and he has remained normal for four years.

Although the operative findings in this case were similar to those in case 2, the history of trauma leads us to assume that the cystic mass was possibly the result of injury. History of trauma is common in cases in which tumor of the brain is suspected, although Parker and Kernohan reported that in only 42 per cent of a series of 431 gliomas of the brain was there previous history of injury which might have been an exciting factor.

In another case in which trauma evidently played an important part, the cyst was diagnosed and localized by means of roentgenologic examination.

CASE 4—Traumatic cyst A boy, aged 13 years, was brought to the clinic because of generalized convulsions. At the age of 3 years he had fallen downstairs, and one month later, after a mild convulsive seizure he was unable to talk for six hours. A generalized convulsion, lasting half a minute and followed by weakness of the right arm occurred shortly afterward. At the age of 4 years, a severe convulsion was followed by hemiplegia, aphasia and incontinence. He had no further attacks until he was 12 years old, when they recurred at weekly intervals for eight months. He was free from attacks until three months before examination, when the seizures recurred frequently, as many as seven in one day. Preceding each seizure, the right leg went to sleep, this sensation progressed up the right thigh and jumped to the right hand, and while ascending the right arm the generalized convulsion occurred.

Roentgenograms of the head revealed a large calcified tumor in the left frontal lobe extending 25 cm beyond the median line (fig 1). Neurologic examination revealed vertical nystagmus, moderate weakness of the lower three fourths of the right side of the face, moderate weakness of the right upper extremity and slight weakness of the distal portion of the right lower extremity. Because the margin of the tumor was more dense than the center a diagnosis of calcified cyst in the left frontal area was made.

At operation the calcified mass was found 2 mm below the surface of the cortex of the left frontal lobe and removed. It was 75 by 8 cm in diameter, weighed 254 Gm and was found to be a mass of cholesterol crystals surrounded by a

calcareous capsule 2 mm thick. The cyst was considered to be the result of an old hemorrhage. There were no epithelial cells or living tissue in the capsule or in the contents of the cyst.

After returning home, the patient continued his school work and graduated from high school; he is quite well at present.

The condition in this case differs from that in case 3, in that it was evidently primarily hemorrhagic, with secondary calcification of the capsule.

Parasitic cysts of the brain are rare in this country, in spite of the freedom with which communication and intermingling of races take place. However, case 5 is an interesting example of echinococcal infestation.

CASE 5—Parasitic cyst. An Italian laborer aged 47, who came to this country at an early age and lived in the middle west, was brought to the clinic for examination. He had been well until two and a half years previously, when he suddenly lost consciousness. A convulsion had not occurred; he was unconscious for from five to ten minutes and this was followed by weakness of the left side of the body. Fourteen similar attacks occurred in twenty-four hours. During the ensuing year and a half, he was able to work and felt well, except for slight weakness of the left arm and leg when he began to complain of right-sided headaches in the morning and projectile vomiting of attacks of petit mal with tremor of the left arm and leg followed occasionally by slight, temporary weakness, of tinnitus, and of hallucinations of smell. He was unable to dress himself and frequently was incontinent.

A serologic test for syphilis and other laboratory tests gave negative results. Roentgenograms of the head gave negative results, as did examination of the eyes. Neurologic examination was essentially negative except for diminution of the acuity of smell on the right side and weakness of the entire left side. The pressure of the cerebrospinal fluid was greatly increased. Each cubic millimeter of the fluid contained 128 small lymphocytes, 43 large lymphocytes and 75 polymorphonuclear leukocytes; otherwise, examination of the fluid gave negative results. On account of the apparent change of personality and left-sided weakness a diagnosis was made of a lesion in the right frontal lobe.

At operation the dura was extremely vascular, and when incised, the convolutions were flattened, broadened and pale yellowish white. An opaque exudate surrounded the vessels of the cortex. In the superior temporal convolution there was a bluish cystic area 3 cm in diameter, when this was opened, clear fluid under pressure was found. Several hydatid cysts from 3 mm to 1 cm in diameter, were found floating free in the fluid of the cavity (fig 2). These had opaque walls, and some seemed to have been torn loose from a stalk. The cavity was explored. It extended into the parietal lobe, and was about 8 cm in diameter, at its base there was a stalk which was ligated and resected. Histologic examination of the fluid the stalk and daughter cysts revealed the characteristic hooklets of *Taenia echinococcus*.

The patient recovered sufficiently to return home but improved very little clinically, although he was still living when last heard from.

Neoplastic cysts vary from the most malignant spongioblastoma multiforme to the least malignant astrocytoma or oligodendroglioma. They may be completely surrounded by tumor tissue, or the walls may be smooth and glistening and contain only one small nodule of neoplastic tissue. The surgical procedure depends on the situation and extension of the cyst, as well as on the degree of malignancy and the size of the associated neoplasm. Some of the more common forms of neoplastic cysts are presented in order to show that differential diagnosis between these and a neoplasm is impossible, except at operation, and that any cyst encountered at operation may be neoplastic.

CASE 6—Spongioblastoma multiforme. A man, aged 54 came to the clinic complaining of frontal headaches and convulsions. He had been in excellent health until six months

previously, when suddenly a generalized convulsion with loss of consciousness developed. A week later, he complained of severe headaches in the morning over the left frontal region. These headaches increased in severity until they were brought on by change of position. Following his first convulsion he had attacks each month, with slight residual weakness of the right upper extremity. A slight change of personality also developed.

General and ophthalmologic examinations gave essentially negative results. Neurologic examination revealed slight weakness of the right upper extremity. The clinical history and course of the disease suggested a progressive lesion of the frontal lobe. This was confirmed by a ventriculogram which gave evidence of obliteration of the anterior horn of the left lateral ventricle with displacement to the right.

Fig. 2 (case 5).—Echinococcus cyst in the right lobe of the brain. a indicates the appearance at operation; b cross section of the cyst.

At operation the left frontal convolutions were flattened and broadened. From a cystic tumor 1 cm below the cortex, 30 cc of yellow fluid was aspirated. The inferior frontal convolution was incised, and neoplastic tissue lined the wall of the cyst. Tissue removed showed it to be a spongioblastoma multiforme, and because of its situation and extent, further operation was not attempted. Temporary improvement followed for a period of six months when the patient died suddenly.

The less malignant type of glomatous cysts should be resected if possible, yet the following case demonstrates that the condition of the patient should influence the extent of the operation.

CASE 7—Astrocytoma. A man, aged 52, came to the clinic stating that he had been well until four and a half years

before, when a generalized convulsion occurred which had been preceded by twitching of the fingers of the right hand and muscular contraction of the right side of the body. Similar attacks occurred three times a day for three days, but were controlled by the use of phenobarbital until four months prior to admission when they recurred every hour. During the last attacks consciousness was not lost, but transient aphasia was present. During the month prior to registration the right hand

FIG. 3 (case 7)—Cystic astrocytoma of the left frontal lobe

and leg became weak, this progressed to paralysis within two weeks.

General and ophthalmologic examinations gave negative results. A moderate degree of aphasia and definite weakness of the muscles of the right side of the mouth and tongue as well as those of the right arm and leg, were present. The tendon reflexes were reduced in the right upper extremity, the patellar and hamstring reflexes were increased, and both Achilles reflexes were decreased. The sensory examination was unsatisfactory because of the aphasia. A diagnosis of tumor of the brain involving the left temporoparietal area was made.

At operation the dura was tense, and when it was incised, a large, infiltrating, vascular, cystic tumor involving the frontal and parietal convolutions was seen. The dura mater was adherent to, and was very vascular over, the tumor. Thick yellowish fluid escaped from the cystic portion of the tumor when aspirated (fig 3). There appeared to be a line of demarcation separating the tumor from the surrounding brain, and complete removal was effected by dissection along this line. Histologic study showed the lesion to be a fibrous astrocytoma.

The patient's condition seemed satisfactory, but one hour after the completion of the operation he died suddenly. At necropsy the tumor was found to have been completely removed.

Glomatous cysts which respond most satisfactorily to surgical treatment are either those which have completely liquefied, or those which contain only a mural nodule of tumor tissue. The complete removal of the nodule prevents refilling and recurrence. Case 8 is a good example of relief following operation, lasting for five years without symptoms of recurrence.

CASE 8—Oligodendroglioma A girl, aged 5 years, was brought to the clinic with the history of being well until six weeks before admission, when she stumbled and fell while going downstairs. There was no evidence of injury, but following this accident she limped with the left leg. Three weeks later, she complained of right temporal headaches in the morning, which lasted only a short time and were not accompanied by vomiting.

General examination was essentially negative, except that the vision of the left eye was 6/6, and that of the right eye, 6/30, the pupils, field and optic reflexes were normal. There was a bilateral choked disk measuring from 2 to 3 diopters. Neurologic examination revealed weakness of the left side of the face and body, and a positive Babinski sign was also present on the left. A diagnosis was made of a lesion involving the right motor areas.

At operation the dura mater was tense. A cyst containing about 120 cc. of yellow fluid was encountered near the posterior horn of the right lateral ventricle. When the cyst was opened with the electrosurgical unit, a nodular tumor was found on the mesial wall (fig 4). This was removed completely so far as could be determined grossly. A small strip of dura was inserted into the cyst for the purpose of drainage. On microscopic examination, the neoplastic tissue proved to be an oligodendroglioma.

The patient's recovery was uneventful. Only slight weakness of the left side remained. Examination twenty months later revealed that the child was normal and had been attending school regularly. She has continued in excellent health for five years and two months.

Often a glomatous cyst embedded in a tumor is encountered, and the situation and extent of the tumor, as well as the condition of the patient, prohibit extensive resection. The cyst may be drained with subsidence of symptoms, and a later operation may be carried out for more complete removal of the tumor. Sometimes the size of the tumor prevents more than a palliative operation as a second stage.

CASE 9—Istroblastoma A man aged 33, registered at the clinic and gave a history of having been in good health until eight months previously, when he noticed that his right hand was weak and that his speech was slower than normal. Two weeks later he suddenly felt his lower jaw tremble, and he became unconscious, these attacks recurred at monthly intervals.

Examination revealed right hemiparesis with increased reflexes, a positive Hoffmann and Babinski sign, a spastic gait and slight aphasia without evidence of increased intracranial pressure. A diagnosis of tumor of the brain involving the left frontomotor region was made.

Operation was postponed for three months at the patient's insistence, at which time it was found that the weakness of the right side had progressed. He also complained of recurring attacks of Jacksonian type, involving the jaw and right side of the thorax, followed by numbness of the right hand.

FIG. 4 (case 8)—Cystic oligodendroglioma with a mural nodule

for one hour. A trocar inserted through the superior temporal convolution encountered a cyst containing 60 cc. of yellow fluid, which clotted on standing. Following removal of the fluid, the cavity was opened and the walls were found to be lined with tumor tissue, which was so extensive that further surgical procedure was not attempted other than applying Zenker's fluid to the walls. After an uneventful recovery the patient returned home, he was able to work for about seven months when the cyst filled. Aspiration carried out at his home was followed by complete relief, but because this was

only temporary he returned for a second operation. The cystic cavity was explored again, and was found to be filled with a degenerating fungus-like mass, the greater part of which was removed.

The patient's convalescence was uneventful, and at dismissal motor power in his right upper arm had increased. He continued to improve for three months, when sudden paresis of the entire right side developed associated with convulsions. He became gradually weaker and died seven months after the last operation.

The tissue removed at operation and at necropsy proved to be astroblastoma. The tumor was very large, and had completely surrounded the cyst.

The malignant nature of the tumor responsible for the cyst is largely responsible for the tendency to recurrence. The benign nature of oligogliomas is well known, and the excellent result in the following case is probably caused by the fact that the tumor belonged to this group.

CASE 10—Oligodendroblastoma A man, aged 43, came to the clinic complaining of headaches and drowsiness. Ten months prior to examination, he began to have headaches in the morning and evening, usually frontal, but occasionally occipital, these had become progressively worse. In the six weeks preceding admission, drowsiness had slowly increased. Spasmodic contractions of the left arm lasting from three to five minutes occurred without loss of consciousness.

Examination gave negative results. The cerebrospinal fluid was xanthochromic and had a positive Nonne reaction. It contained 99 small lymphocytes, 261 large lymphocytes and 51 polymorphonuclear leukocytes in each cubic millimeter. A diagnosis of a lesion of the right frontal lobe was made.

A cyst containing 30 cc. of yellow fluid was found to be enclosed by a large infiltrating tumor, and because of the condition of the patient and the size of the tumor, removal was not attempted. The cavity was swabbed with Zenker's solution, and a strip of dura was turned into the cyst for permanent drainage. Histologic examination of the tissue removed showed it to be an oligodendroblastoma.

The patient's convalescence was stormy but he improved following repeated spinal punctures. After receiving two courses of roentgen treatment he went home and has continued working for twenty-three months without any recurrence of symptoms.

The compilation of numerous histories of intracranial lesions demonstrates the futility of making a pathologic diagnosis of the lesion from the duration of the illness. The brain becomes accustomed to slowly progressing compression, and a lesion which has been present and enlarging for a long time may produce a short clinical history of symptoms. For that reason exploration is essential in the majority of cases in which the history and examination indicate increased intracranial pressure.

In the presence of the more benign types of tumor a second operation may be required much later than in the more malignant types. In the following case the patient was completely relieved for six years, and this is a common occurrence in the slower growing types of tumors.

CASE 11—Gangliocytoma A girl, aged 16 years, was brought to the clinic because of frontal headaches, vomiting and difficulty with vision. She had been perfectly well until five months previous to examination. She had a generalized convulsion three days before examination.

Examination of the eyes revealed bilateral acute choked disks of 6 diopters, with right homonymous hemianopia. At operation a large cystic glioma was found in the left temporal lobe. This contained about 90 cc. of yellow gelatinous fluid, which clotted on standing. The major portion of the tumor was removed with some of the surrounding tissue. On histologic examination, the tumor proved to be a gangliocytoma with many neuroblasts and some mitotic figures. Following opera-

tion, convalescence was satisfactory, the choked disks receded, but the vision did not entirely return to normal, on account of the presence of secondary optic atrophy.

The patient remained well for six years, when she returned to the clinic complaining of vague generalized pains in the joints and headache, which had been present for four weeks, associated with vomiting. Examination revealed that the former decompression wound was bulging, and signs of increased intracranial pressure were present. A second operation was done, and the left temporal lobe was found to be filled with a granular red tumor which was partially removed. Histologic examination proved this to be well differentiated gangliocytoma. The patient was relieved of all symptoms. A course of roentgen treatment was given. She returned home, and after a period of five months, died suddenly.

Evacuation of the contents of a glomatous cyst is followed by transient relief of symptoms in the majority of cases. This palliative procedure is frequently important in order to prepare the patient for a more extensive operation. Case 12 illustrates the importance of palliative measures when a lesion of the brain complicated pregnancy. The patient was relieved of intracranial symptoms until the completion of gestation and a cesarean delivery. The tumor was then removed.

CASE 12—Protoplasmic astrocytoma A woman, aged 28, came to the clinic complaining of headache and visual disturbance. She had been in excellent health until four years before examination, when she began to suffer from severe attacks of headache and blurring of vision. These attacks came on at intervals of one year for three years, and lasted from three to four weeks. She became pregnant two months before examination, since which time she had had six or seven attacks of numbness involving the entire body, associated with severe headaches. Following the last attack, she became comatose for one hour.

General and neurologic examinations were essentially negative, except for the condition of pregnancy. Roentgenograms gave evidence of increased intracranial pressure. A bilateral acute choked disk of 3 diopters was found in each eye, with a right homonymous hemianopia. A diagnosis of tumor of the left temporoparietal region was made.

At operation a large cystic glioma was found involving the left temporoparietal region, from which 50 cc. of thin yellow fluid was aspirated. Because of the pregnancy, it was decided to postpone a more radical operation until later.

Following operation, the patient's condition improved, she was relieved of her headaches, and she was given three courses of high voltage roentgen therapy. The choked disks receded, and the visual fields improved. She was observed during the period of pregnancy, and when she came to term, a cesarean section was done, following which the patient and infant were in excellent condition.

One month after the cesarean section, the bone flap was elevated again and the cyst explored. On the posterolateral wall of the cyst, a nodule of tumor was found and completely removed. This was found to be protoplasmic astrocytoma. Following an uneventful convalescence, the patient returned home, and has been in excellent health for three years.

The following case illustrates similarly the relief which often follows partial removal of a neoplasm of low degree of malignancy. It is sometimes impossible completely to remove a cystic tumor, and when dealing with the less malignant types of neoplasm, it is advisable at times to remove as much tissue as is commensurate with the safety of the patient, and palliative relief lasting for years may ensue.

CASE 13—Ependymoma A woman, aged 43, came to the clinic complaining of headaches which began six years previously. Jacksonian attacks followed by paresis of the right side, with transient hemianopia, had occurred frequently during the previous six months.

General and ophthalmologic examinations gave negative results, but neurologic examination revealed marked weakness

of the entire right side of the body, with increased reflexes. A diagnosis of tumor involving the left motor cortex of the brain was made.

At operation, the left precentral convolution was found to be broadened and flattened. It fluctuated on palpation, and 15 cc of yellow gelatinous fluid was aspirated. The cortex was incised and a dark purplish-red, mucoid, granular tumor was found, which was almost completely removed. After an uneventful convalescence, the patient was dismissed with a slight residual right hemiplegia. This gradually decreased, and she has been able to do her own housework and take part in the activities of the community for the last three years.

It is unusual to encounter a cystic condition with meningiomas, and because of its rarity the following case is presented.

CASE 14—Endothelioma. A laborer, aged 55, registered at the clinic stating that he had been perfectly well until six months previously, when the day following a minor injury to the back of his head and neck he suffered from a generalized convulsion which recurred from every two to four weeks.

Examinations gave essentially negative results and the patient was advised to take phenobarbital and to return later for another examination. Three months later he returned, and stated that he had had a generalized convulsion with a residual weakness of the left side. Another attack had been preceded by twitching and spasm of the left hand, followed by transient left homonymous hemianopia. Also he had frequently noticed muscular twitching in the left forearm when

Fig. 5 (case 14)—Cystic parasagittal meningioma.

sitting quietly. At this time, neurologic examination revealed definite, although slight, left hemiparesis, with increased tendon reflexes and tremor of the left hand. A diagnosis was made of tumor of the brain involving the right frontomotor area.

When the dura was opened, a large reddish, soft tumor was found on the surface anterior to the Rolandic area; it extended to the median line and was attached to the longitudinal sinus (fig. 5). The tumor was cystic, and it collapsed following aspiration. The cystic fluid was yellow but did not clot. The tumor was completely removed, with a portion of the longitudinal sinus. Grossly, it had the appearance of a hemangio endothelioma, but the microscopic examination showed it to be a meningioma.

Compilation of the characteristics of cerebral cysts encountered at the operating table reveals similarities

TABLE 1—Cerebral Cysts

Type of Cyst	Color of Fluid
Congenital	Clear
Traumatic	Clear
Parasitic	Clear
Inflammatory	Clear
Gliomatous	Yellow

which may be confusing in arriving at a definite diagnosis. A comparison of the cystic fluids revealed that in general the congenital, traumatic, parasitic and inflammatory fluids were clear except from the recent

and calcified traumatic lesions. Yellow was the characteristic color for the neoplastic cysts (table 1).

The chemical analysis of these fluids did not reveal any outstanding change from cerebrospinal fluid except a tendency to contain an increase of the total proteins.

TABLE 2—Gliomatous Cysts

Type of Tumor	Amount of Fluid Cc	Color	Percentage of Cysts
Astrocytoma	20-100	Yellow	10
Oligodendrocytoma	10-120	Yellow	34
Polar spongioblastoma	40-60	Yellow	23
Ependymoma	10-20	Yellow	70
Spongioblastoma multiforme	10-20	Yellow	40
Gangliocytoma	10-15	Yellow	9
Hemangio endothelioma	10-16		43
Meningioma	50		10

For the purpose of comparison the neoplastic cysts were examined to determine the amount of fluid which was present and the tendency to form cysts (table 2).

SUMMARY

Cerebral cysts encountered at operation may be congenital, inflammatory, traumatic, parasitic or neoplastic. To the neurosurgeon, the most important and common group encountered is that which occurs with neoplasms; these were found to be associated with practically all types of primary tumors of the brain above the tentorium. A much rarer type of tumor in this situation, containing cysts, is the meningioma, of which only two were encountered.

It was found that only the neoplastic cysts consistently contained xanthochromic fluid, whereas all the other cysts contained clear fluid. It was noted further that in general the more benign the glioma, the more prone it was to undergo cystic degeneration.

Decompression and simple drainage was often followed by a long period of palliative relief, thus allowing the more radical procedures, such as partial or complete removal of the tumor when the patient's condition warranted. Following initial drainage, subsequent aspirations were sometimes necessary to prolong the palliation. Several operative procedures were sometimes necessary for the more benign tumors in order to remove them completely.

ABSTRACT OF DISCUSSION

DR. JAMES W. KERNOHAN, Rochester, Minn.: For several years I have had the idea that there were limited types of tumors in which cysts could be found and consequently I was very much interested in this study in which Dr. Craig found that practically every type of glioma underwent cystic degeneration. Occasionally we found the tissue of the tumor completely surrounding the cyst and, on the other hand, we often found the so-called mural nodule that was mentioned. Theoretically it seems possible for a tumor to disappear completely and to leave only a cyst, which would be almost impossible to distinguish at operation or histologically from the so-called simple or traumatic cyst. It is impossible to make a differential diagnosis of a simple cyst, traumatic cyst or inflammatory cyst by microscopic examination alone. Such diagnosis must be made in conjunction with the history the patient gives of the antecedent of the cyst. There are at least two hypotheses that may be thought of in connection with the possible cause of cyst formation which occurs along with tumors. One is that there is a transudate from the wall of the tumor such as is supposed to occur in Lindau's disease. The other possibility is that in tumors the blood supply does not progress as rapidly as the growth of the neoplasm. The blood supply in the center is insufficient and degeneration occurs or the more slowly growing and denser tumors have an insufficient blood supply and degeneration occurs in the center.

DR HANS H. REIST, Madison Wis. The presentation of Drs. Crug and Kernohan is the first comprehensive clinical surgical study on cerebral cyst. The authors demonstrate that the most careful clinical investigation of all etiologic factors too often fails in the differentiation of intracranial lesions. The diagnosis of cerebral cysts is a difficult one because no objective signs or clinical symptoms permit the differentiation of a cyst from a tumor, at times from encephalomalacia or liquefied infarcts. It is true that the history or the variation of hiccups on straining coughing and sneezing suggests a cyst, or that encephalographic studies demonstrate a communicating porencephalic cyst with the ventricular system, or with the pira-archnoid spaces. Commonly cases of serous meningitis or of circumscribed cystic meningitis are caused by trauma or infection. They are not cysts, properly, but they have been described under the misnomer pseudotumors. I agree that the most common form of cerebral cyst is the neoplastic. If one encounters a simple cyst a careful microscopic examination of the cyst wall should be performed for hemangioma to rule out the classification of such a cyst as belongs to Lindau's syndrome. Although it is extremely rare to find this kind of cyst in the cerebrum one has to keep the possibility in mind. The parasitic cysts have been seen more often in Europe especially since 1914. Sato reported 128 cases of infestation with *Cysticercus cellulosae* with forty eight positive manifestations in the fourth ventricle and Sproule reported eighty cases in the literature with such abnormalities in the fourth ventricle. Naturally, in these cases of parasitic cysts the blood eosinophilia necessitates a search of the spinal fluid not only for eosinophil cells but also for *Cysticercus* membranes or hooklets of the echinococcus. Analysis of the clinical data available on cerebral cysts did not reveal any complaints or clinical signs that would permit differentiation of a cyst from a tumor. I have the feeling that cysts are more stationary, with more extreme fluctuation in the subjective complaints. I agree with the authors that only early exploration and aspiration will clear the situation. The approach and treatment have been so well covered in this paper that it is not necessary to make any comment.

DR J. RUDOLPH JÄGER, Denver. The tumors that are associated with cysts are usually the ones most amenable to surgery, for example, the pachymeningitis cyst or the glommatous cyst with a small intramural tumor. The possibility of a cyst being present in an extremely ill patient showing signs of intracranial pressure must be constantly kept in mind. By ventricular estimation combined with a careful neurologic examination the tumor mass in many instances may be sufficiently localized so that through a trephine opening the cyst can be evacuated and the patient's condition improved to a point at which an extensive craniotomy may be performed. It must be realized that a great percentage of brain tumors above the tentorium as well as below it, by pressing on the third ventricle or aqueduct of Sylvius produce a cystic collection of cerebrospinal fluid in the lateral ventricles or in the ventricle on the side opposite the tumor. One puncture of the cystic ventricle will frequently save the life of the patient for further surgery, or as I have been doing recently, by the insertion of a small ureteral catheter into the ventricle through a ventricular needle, thereby gradually decompressing the ventricle over a period of several days. A large percentage of patients with tumor come to the neurosurgeon in an extremely critical condition. Many even in such a state can be saved if a cyst can be evacuated or a cystic ventricle can be decompressed. The young woman mentioned by the authors came under my care when I first began to do neurosurgery. Dr. Learmonth, doing an exploratory operation found a cyst in the temporal lobe and had put the bone flap back in place because of some operative difficulties. He sent her home to improve for a craniotomy later. I received a call when I was 200 miles up in the mountains on a vacation to hurry back to Denver. At that time the woman was in stupor and almost in coma. I found her in a critical condition from pressure. By perforating through a trephine opening that had been left by Dr. Learmonth and by evacuating the cyst of about 2 ounces of fluid I was able to improve her condition. She returned later to Dr. Learmonth for removal of a mural tumor and she is well today three years later.

RECENT IMMUNOLOGIC STUDIES IN HYPERSENSITIVITY TO TOBACCO

MARION B. SULZBERGER, M.D.

NEW YORK

The studies which form the actual experimental basis of this report were carried out, principally, on patients with typical thrombo-angitis obliterans and on a control group of smokers and nonsmokers without this disease.

Before entering into the discussion of my experimental results, I should like to mention certain fundamental immunologic concepts which led to the theory that thrombo-angitis obliterans, a disease in which the role of tobacco has frequently been mentioned and acknowledged by most observers, might be a localized hypersensitivity of certain groups of blood vessels to circulating allergens derived from or contained in tobacco.

The first of these concepts is that of localized and circumscribed fixed specific hypersensitivity. Although examples of this may be found in every form of hypersensitivity and in every organ, they are best known, as is only natural, in the skin, and are most clearly evident to the immunologically minded dermatologist.

Perhaps the most frequently encountered example of localized and fixed specific altered reactivity is the mycotic eruption known as dermatophytid of the hands. In this condition, as is now well known, fungi, often originating from foci on the feet, although entering the blood stream and thus presumably coming in contact with all the tissues of the body, often cause manifest lesions only in the areas of fixed localized altered reactivity on the hands.¹

Another, perhaps even more striking, example is to be found in the so-called fixed drug eruptions. Here the drug—phenolphthalein, for example—taken by mouth enters the blood stream and must be distributed in approximately equal quantities throughout all the organs of the body and all parts of the skin. And yet, in certain hypersensitive persons, it is of frequent occurrence that only a round or oval, sharply circumscribed area of the skin reacts to the circulating drug. It is known that hypersensitivity to phenolphthalein often becomes manifest in a circumscribed area on the glans penis and, sometimes, at this site alone. On the other hand, there are drugs—the arsphenamines, bromides and iodides—which have a predilection for other sites. Just as these circulating drugs selectively sensitize and attack certain parts of the skin—the follicles and cutaneous and subcutaneous vessels—so other drugs and circulating substances may be able selectively to sensitize and to attack other organs or parts of organs. I believe that such examples may be found in the cases of acute yellow atrophy of the liver sometimes caused by incredibly small doses of cinchophen derivatives and in the cases not infrequently caused by arsphenamine, in the cases of purpura cerebri (encephalitis haemorrhagica) caused by arsphenamine, or in the cases of asthmatic attacks following the ingestion or injection of quinine.

Read before the Section on Dermatology and Syphilology at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 14, 1933.

From the Dermatological Service of Montefiore Hospital and the Department of Dermatology of the New York Post Graduate School of Columbia University.

¹ Jadassohn, Werner and Peck, S. M. cited by Sulzberger, Marion B. and Lewis, G. M. Trichophyton Hypersensitivity Demonstrated by Contact Tests. Arch. Dermat. & Syph. 22: 410 (Sept.) 1930.

Embodied in this concept there is, to a certain degree, merely a modern paraphrasing of the old statement that certain persons possess an area or areas which are more susceptible to attack—*loci minoris resistentiae*. But the newness of the concept lies in attributing some of these pathologic reactions to a fixed and specific immunologic process, and this opens new ways for study and experimentation.

The consideration of certain fixed areas of lowered resistance as sensitization phenomena brings in its train other immunologic concepts. The next to be mentioned is that of the predilection of certain allergens to sensitize and elicit reactions in certain tissues, often to the exclusion of all other tissues. One might even say that each allergen has its favorite point of attack. Most of the aforementioned examples illustrate this point. There are many other dermatologic conditions which show this sharply focused selectivity. For instance, certain circulating allergens, such as quinine and formaldehyde, frequently attack the epidermis alone, while others—for example, shellfish, strawberries and the iodides—often confine their deleterious effects to the vascular layers of the upper cutis. We thus distinguish between eczematogenous and urticarigenic noxae.

The third immunologic concept is that not only sudden and evanescent reactions are caused when the excitant meets the specifically sensitized shock tissue but also chronic reactions and permanent organic damage are often caused by one or successive shocks resulting from such encounters. This concept is one which has not, in my opinion, received the recognition it deserves. It has been my experience, in discussing the theme of the present paper with immunologists and physicians, that the majority are disinclined to accept permanent damage as characteristic of certain forms of hypersensitivity, and consider this concept to be unorthodox or new. And yet, there are innumerable classic examples of allergic reactions resulting in permanent damage.

The oldest and perhaps the best known example is that of the Arthus phenomenon in horse serum sensitization. Here vascular thrombosis and obliteration lead to necrosis and slough.

Classic dermatologic examples of such destructive and nonephemeral reactions are to be found in the vegetating and ulcerating iododermas and bromodermas, in which the active processes are often of astonishingly long duration, the destruction thus brought about leads to scarring. There are even cases on record in which iododermas and bromodermas have proliferated in a manner similar to that of malignant tumors (sarcomas, or the almost neoplastic tumors of lymphogranulomatosis and mycosis fungoides), in spite of absolute elimination of contact with the eliciting drug, these conditions have eventually brought about the patient's death (Eller and Rein and Bloch and Fenchio²).

Common examples of destructive lesions originating in the vascular apparatus of the skin resulting from sensitization to and contact with micro-organisms or their products are tertiary syphiloderms (hypersensitivity of the skin to luetin), erythema induratum Bazin (hypersensitivity of the skin to tuberculin) and pyropulonecrotic tuberculids.

The fourth immunologic concept includes the principles of idiosyncrasy and the harmless nature of allergens to the nonhypersensitive. My interpretation of

idiosyncrasy, as applicable to most cases, is that it is a differentiation from the norm which lies in a quantitative abnormality rather than in a qualitative one. By this I mean that the idiosyncratic person becomes sensitized to concentrations and quantities of excitants that do not bring about sensitizations in normal persons. This quantitative hypothesis receives support from the observations that wherever excitants have been sufficiently concentrated in vitro or have been sufficiently diluted, the percentage of persons who could be sensitized has been in proportion to the degree of concentration. In other words, the greater the concentration of a given allergen, the larger is the number of persons who could be sensitized (Bloch, primrose, R. L. Mayer paraphenylenediamine, and Doerr, horse serum in guinea-pigs). According to this hypothesis milk, eggs, wheat, pollens or any other common causes of sensitizations could be sufficiently concentrated, these concentrations should sensitize all persons exposed to their contact. However, this has not, as yet been proved and one must accept the fact that substances absolutely harmless and incapable of sensitizing normal persons in concentrations in which they are commonly encountered cause sensitizations and severe reactions in certain (idiosyncratic, atopic and allergic) persons. These idiosyncrasiogens, excitants and allergens are generally not poisons in the pharmacologic toxicologic sense, nor are they primary toxins of bacterial nature. They become harmful only after, and due to sensitization (certain bacterial diseases are, in all probability, due to a similar process in pathologic conditions due to the tubercle bacillus or to *Spirochaeta pallida* which elaborate no known toxins, the sensitization and the immunologic phenomena are among the essential and causal factors).

The fifth immunologic concept is that in man the vascular system is one which seems to be peculiarly susceptible to sensitizations and is thus most frequently the seat of reactions. This concept may appear to be at variance with the older view concerning the seat of reaction in such a classic sensitization as human asthma. It has long been believed that in this condition the smooth muscles of the bronchioles comprised the shock tissue. But more recent studies make it seem possible or even probable that—even in asthma—the blood vessels in the lungs are the first areas to react and that the damage to these vessels their increased permeability, the extravasation of fluid and cells and the tissue edema play a large, if not a preponderant role in bringing about the shock syndrome.

I do not believe that any one can doubt that the blood vessels of the conjunctiva and of the nasal mucosa may well be the seats of reaction in hay fevers and vasomotor rhinitis (see the recent experiments of Al Walzer). In the skin, with the exception of the eczematous reactions which are confined to the epidermis, the blood vessels of the cutis and subcutis are almost always the shock organs. Examples proving this may be found in erythema nodosum (due either to micro-organisms and their products, or to drugs, such as bromides, iodides and phenolphthalein), follicular trichophytids and tuberculids, livedo racemosus and, perhaps most common of all, petechiae, the purpuras, angioneurotic edemas, urticarias and disseminated neurodermites.

By means of the usual technique of testing the skin (the scratch or intradermal methods), the allergen is brought in contact with the superficial vessels of the cutis and the sensitive tissues. The reaction, either

² Bloch, B. and Teneho, T. Zur Klinik und Pathogenese des Bromoderma vegetans. Arch. f. Dermat. u. Syph. 165: 93, 1932.

directly or indirectly, eventually damages the wall of the capillary and permits extravasation of fluid and certain blood cells. In my opinion, this reaction may certainly be regarded as another example of vascular hypersensitivity.

It appears to me to be a plausible hypothesis that the skin serves as a test tissue in so many different forms and so many differently localized internal hypersensitivities because through tests on the skin, one brings to light a hypersensitivity of a certain part of the vascular system (i. e., the upper cutis or papillary capillaries) which may be associated with hypersensitivity of the same shock tissue elsewhere, i. e., with a hypersensitivity of the blood vessels in other and, perhaps, far distant organs.

This leads me to the sixth and last immunologic concept to be mentioned namely the usefulness of the skin as a test tissue in a great variety of hypersensitivities of internal organs. This utility has already been recognized and adequately employed in many diseases of hypersensitivity such as asthma, hay fever, migraine, tuberculosis and so forth. I believe that we are only beginning to realize the possibilities of this method. All diseases which have the characteristics of hypersensitivity and idiosyncrasy, even though the pathologic process is sharply localized in a certain organ or even part of an organ should be studied as possible sensitizations and investigated by means of tests on the skin. The conditions which fall into this class are too numerous to mention, and I shall name only a few of those in which my experience has shown this to be a fruitful approach: appendicitis syndrome (proved by hypersensitivity to arsphenamine in one case), neuralgia (proved by hypersensitivity to tobacco in two cases), keratitis (proved by hypersensitivity to iodide in one case), and alcoholic psychosis (proved by hypersensitivity to rye whisky in one case).

Many other diseases must, of course be studied in this manner, for instance, uveitis, retrobulbar neuritis, angina pectoris, coronary disease and gastric ulcer (Harkavy).

While these are all examples in which the fundamental immunologic concepts I have mentioned may be at play, my results in testing the skin of patients with thrombo-angitis obliterans with tobacco bring to light more clearly the various principles I have mentioned.

TECHNIC

The method of testing the skin which my collaborators and I used in carrying out these studies is the classic one employed in hay fevers and asthmas. Approximately 0.01 cc of the excitant is injected intradermally and the site observed for at least one-half hour to note the growth of the wheal and the development of the surrounding erythema.

We employed ten different extracts of tobacco, six of which were prepared by the usual methods of extraction (Coca) from standard brands of cigaret and pipe tobaccos, two from two different kinds of uncured tobacco leaf and two from mixtures of a great variety of tobaccos. These tobacco extracts were all demicotinized to such a high degree that large doses (1 cc) were no longer fatal to mice. In addition to these demicotinized extracts, we employed a solution of 0.4 per cent nicotine sulphate which, when diluted two and one-half times further, and when injected subcutaneously in doses of 0.2 cc, killed mice within from two to five minutes.

RESULTS

As a first group, twenty-four patients with typical thrombo-angitis obliterans were tested with the solutions mentioned in the manner described. Nineteen of these, or 78 + per cent, gave immediate positive wheal

reactions to one or more of the tobacco extracts, the reactions ranging from + to +++ (+). These findings agree, in great measure, with those of Harkavy and his associates, who made similar investigations.³

As a second group, I tested ninety-five smokers in a hospital population which included many cases of a great number of different diseases which were not selected in any way except to exclude cases of thrombo-angitis obliterans. I also tested fifty healthy adult smokers (physicians, nurses and hospital personnel). The percentage of positives in this group was 36 +. There were no differences in the percentages of positive reactions among the hospitalized patients and the healthy personnel. There were no differences in the percentage of positive reactions elicited in male and female subjects and no differences in the cutaneous reactions of Jews and non-Jews. Thus, in my second group—that of smokers—36 per cent of the persons tested reacted to tobacco. (For a more complete discussion of these findings see Sulzberger.⁴)

A third group which was tested comprised fifty-eight nonsmokers. Only nine of these, or 16 per cent, had positive reactions of the skin to tobacco.

I believe it justifiable to conclude from these figures (1) that a sensitization to tobacco exists, (2) that tobacco smoking brings about a sensitization of the superficial vascular layers of the cutis to tobacco extracts, and (3) that a markedly higher percentage of persons afflicted with thrombo-angitis obliterans have a sensitized cutaneous vascular system than is to be found in other smokers.

I should like to discuss the experimental results at the conclusion of the report of each group of experiments. But, at this point, I must first say a word about tests of the skin in general. Elsewhere, in a discussion of the patch test, I have elaborated on the criteria in judging positive tests and evaluating their clinical significance.⁵ What I have said concerning patch tests seems to me to apply to other types of tests of the skin and to the immediate wheal reaction which is here observed. A test must be considered positive only when (1) it is not elicited by a so-called primary irritant, that is, not by a substance in a concentration which will cause reaction in all or in a large majority of skins, (2) the reaction is identical with or analogous to the condition under investigation, (3) the person being tested can be proved or assumed to have had prior contact with substance eliciting the reaction, or with a substance belonging to same immunobiologic or chemical group, (4) a control or controls elicit no reaction.

A reaction is of clinical significance only when these four criteria have been fulfilled and when, in addition the following facts are established: (1) The substance eliciting the positive test is one which the clinical findings point to as a possible factor in the causation of the disease, (2) elimination of contact with the substance brings about amelioration or cure, and (3) renewed contact with the substance causes a recurrence or exacerbation of the clinical disease. I believe that

2a In the editorial on this subject which appeared in THE JOURNAL Aug 12 1933 page 527 it was stated that the positive tests in these cases were obtained by the patch method. This is an error. The positive reactions were of immediate wheal and erythema type in response to intradermal tests that is they were not epidermal but vascular.

3 Harkavy Joseph Tobacco Sensitiveness in Thrombo-Angitis Obliterans Migrating Phlebitis and Coronary Artery Disease Bull New York Acad Med 9 318 (May) 1933 Harkavy Joseph Hebal S and Silbert S Tobacco Sensitiveness in Thrombo-Angitis Obliterans Proc Soc Exper Biol & Med 30 104 (Oct) 1932

4 Sulzberger Marion B Recent Immunologic Experiments in Tobacco Hypersensitivity, Bull New York Acad Med 9 294 (May) 1933

5 Sulzberger Marion B and Wise Fred The Contact or Patch Test in Dermatology Arch Dermat & Syph 23 519 (March) 1931

by adhering rigidly to these criteria immunologists may avoid the most important sources of error in judging tests of the skin and thus also in the future avoid much of the criticism to which this method of investigation has been subjected.

As far as I can see the postulates mentioned have, to a great degree, been fulfilled in thrombo-angitis obliterans. It is too well known to require further discussion that the occurrence of this disease is in most instances, intimately connected with tobacco smoking. Many of the patients are excessive smokers. Cessation of smoking tends to arrest the pathologic progress and resumption of smoking often causes renewed activity.

That tobacco smoking causes a sensitization to tobacco seems to me to be proved, as before stated by the higher percentage of reactions of the skin found in smokers than in nonsmokers and that this sensitivity is present in a strikingly high frequency in thrombo-angitis obliterans is shown by the figures I have quoted. The pathologic processes in thrombo-angitis obliterans are localized in the blood vessels and the reaction of the skin observed in the positive test is, though evanescent, also vascular.

The tobacco allergens I employed were not primary irritants, and the positive reactions of the skin noted must have been due to sensitization. One is forced to this conclusion when one considers that 84 per cent of nonsmokers and 64 per cent of smokers show not the slightest trace of reaction to the tobacco allergen.

As a result of my experiments and in conjunction with previous clinical experience, I feel that I may safely advance the opinion that the positive reactions of the skin to tobacco found in thrombo-angitis obliterans are highly suggestive of this condition, being in most cases connected in some way with a hypersensitivity of certain parts of the vascular system to circulating allergens contained in or derived from tobacco.

My second group of experiments investigated the question of whether thrombo-angitis obliterans was accompanied by a sensitization of the skin to tobacco alone or to tobacco and other allergens. With the assistance of Drs. C. Feit, H. H. Gelfand, N. N. Smith and L. Mamelok, eighteen of the patients with thrombo-angitis obliterans were tested with a large number of common allergens in addition to tobacco. In one case there were no cutaneous reactions whatsoever, two patients gave negative reactions to tobacco but marked reactions to other inhalants (dust, feathers, kapok and cat hair), fifteen patients were positive to tobacco but many not to tobacco alone, there being ten cases in which some other allergen or allergens also caused definite positive reactions of the skin. The additional positive reactions in this group were caused by foods and inhalants, dust being the principal one (eight positive reactions to dust, two positive reactions to ragweed, six positive reactions to barley and five positive reactions to orts). I therefore conclude that patients with thrombo-angitis obliterans have a polyvalent sensitivity of the vascular apparatus of the skin to various excitants which includes, beside tobacco, other inhalants and also foods. This speaks in favor of thrombo-angitis obliterans as a disease of sensitization. As is known from experience, sensitizations caused by one substance tend to lose their monovalence and become polyvalent, with a sensitivity of the skin embracing many substances which may or may not be of clinical significance. Unless thrombo-angitis obliterans is a disease of sensitization, it would be a hitherto unprecedented finding to have such a large number of positive skin reactions

in patients not within the atopic group (I did not find thrombo-angitis obliterans to be an atopic disease).

These results also explain why typical thrombo-angitis obliterans can occur in nonsmokers. All I should like to say of the disease at present is that if it is, as I believe it to be a hypersensitivity, this hypersensitivity is in most, but by no means in all, cases due to tobacco. Other substances can, in all probability, cause the same picture, and this again coincides with the rule in other forms of hypersensitivity. I know of no clinical manifestation of hypersensitivity which is invariably caused by one particular substance, and by that substance alone in all cases. (For instance, spirochetes or lepra bacilli can sometimes cause histologic tubercles not to be differentiated from those seen in the usual reactions to tubercle bacilli or their products. Ragweed and timothy account for most cases of atopic vasomotor rhinitis in or about New York City, but an occasional nonseasonal but otherwise clinically identical case will be seen which is caused by another inhalant, such asorris root or by a food, such as milk.) The two patients who gave negative reactions to tobacco but marked reactions to other inhalants seem to be peculiarly significant in this respect. Such cases require further study, in particular as to whether one or more of the substances eliciting the positive skin reaction may not be of clinical or etiologic importance.

In a third group of experiments, in collaboration with Dr. L. Feit, I investigated the relationship of the form of hypersensitivity demonstrated in thrombo-angitis obliterans with other forms of human hypersensitivity in particular with atopy. We found no proof that there was any relationship between the hypersensitivity of thrombo-angitis obliterans and the form of hypersensitivity found in asthmas, hay fevers, some infantile eczemas and disseminated neurodermites.

The family histories of our patients with thrombo-angitis obliterans were essentially negative for the presence of atopic diseases. The patients themselves had no atopic diseases and had no personal history of atopic disease. (Only one patient with a possible history of hay fever was found.)

Dr. Feit and I most carefully investigated our entire group of cases for reagins (passive transference antibodies, Prausnitz-Kustner antibodies) to tobacco. In spite of repeated and persistent experiments, antibodies of this type could be found in only one case. We also occasionally succeeded in demonstrating such antibodies to tobacco in other diseases. Furthermore, our patient with thrombo-angitis obliterans with tobacco reagins had reagins to dust also. In view of this, even in the one case in which tobacco reagins were found, the findings cannot be regarded as pathognomonic.

I therefore conclude that the sensitization in thrombo-angitis obliterans is nonatopic, for, in the material herein reported, the characteristics of atopic hypersensitivity are completely lacking (Sulzberger and Feit⁶).

Hypersensitivities with immediate wheal reactions of the skin, without atopy and without reagins are well known in other sensitizations of human beings. Urticarial and asthmatic reactions to drugs frequently fall in this group. Sensitizations to normal horse serum (not necessarily those to immune horse serums), sensitizations to many forms of insect bites and asthmas from *Pediculoides ventricosus* are in this category and thrombo-angitis obliterans will, if my experiments are

⁶ Sulzberger, Marion B. and Feit, E. Studies in Tobacco Hypersensitivity. II. Thrombo Angitis Obliterans with Positive Urticarial Skin Reactions and Negative Reagin Findings. *J. Immunol.* 24: 425 (May) 1933.

verified also fall in this group (For a more complete report and discussion of these experiments, see Sulzberger and Feit⁷)

The fourth and last group of experiments I shall mention concerns the question of the nature of the sensitizing substance or substances in the heterogeneous chemical mixture known as tobacco. I cannot as yet give any definite answer to this question. This interesting analysis must be carried further by chemical and physical fractionation of tobacco extracts and by means of tests of the skin. I can state, however, that the active ingredient eliciting the positive reaction of the skin to tobacco resists moist heat of 58 C. for one hour, that it resists irradiation with unfiltered x-rays in a dosage of six erythema units, that it resists exposure to ultraviolet rays for one hour and that it is not destroyed by boiling for one minute.

There is one further and to my mind new and important statement which can be made concerning the nature of the tobacco ingredient or ingredients which cause the reaction of hypersensitivity. My experiments in what I term "immunobiologic analysis" lead me to conclude that, in general, the reaction is caused by parts of the tobacco other than nicotine. So far as the immunologic effects of tobacco are concerned, nicotine seems to play either no role or a negligible one. I have been using patch tests with tobacco and with nicotine solutions for many years, and while I have seen several eczematous reactions to tobacco extracts, I have seen none to nicotine (Stauffer⁸). In the course of intradermal testing with tobacco extracts and with nicotine, I have seen not a few late tuberculin type of reactions appear at the site of application of tobacco but none at the site of application of nicotine. (The significance of this late tuberculin type of reaction to tobacco is, as yet, unknown and unstudied.)

In regard to the urticarial wheal reactions which here concern us primarily, I have found that nicotine is surprisingly inactive and innocuous. I have published elsewhere (with E. Feit and B. Scholder) a comparison of immediate reactions elicited by denicotinized tobacco extracts and by a strong solution of nicotine sulphate (0.4 per cent). In the twenty-five cases published (thirteen were patients with thrombo-angitis obliterans), only one showed a slight reaction at the nicotine test site. In all the other cases, the denicotinized tobacco site caused a reaction of the skin definitely stronger than that at the site of the injection of the pure nicotine (Sulzberger⁶).

Since the publication of these twenty-five cases, I have continued to test with denicotinized tobacco and with the nicotine solution. While my collaborators and I have seen many hundreds of positive reactions to tobacco, we have observed only two cases in which there were slight to moderate reactions to nicotine.

It is obvious that as soon as one regards the pathologic effects of tobacco as possibly due to sensitization, it is no longer necessary to attribute its deleterious action to any alkaloid or poison it may contain. (See the aforementioned fourth immunologic concept, which refers to the almost universally harmless, nontoxic and nonpoisonous nature of allergens.)

It is well known that all attempts experimentally to reproduce and study the harmful effects of tobacco, which are often so evident clinically in smokers, have failed. These attempts have, to my knowledge, been

made without employing the method of sensitizing the test object or experimental animal. Many of them were purely toxicologic experiments with nicotine, and these often resulted in such manifest failures that many observers have sought to find poisons other than nicotine on which to blame the damage caused by smoking.

A voluminous literature exists which treats of poisons other than nicotine to be found in tobacco smoke (pyridine bases, furfural and carbon monoxide). In my opinion this entire phase of research in tobacco smoke spring into being because of the failure of the experiments with nicotine and because experimenters, not considering the possibility of sensitization, found it necessary to search for other poisons. So far as I know none of the other poisons has been proved to reproduce the harmful effects of smoking.

All of these failures speak to my mind in favor of sensitization mechanisms being at play in the pathologic conditions clinically so evidently due to tobacco.

The concept of tobacco becoming harmful through sensitization will I hope, be fruitful in the future. If correct, its application should enable investigators experimentally to reproduce and study the effects of tobacco, by sensitizing the experimental object. This will be a decided advance and may lead to results of great practical value. This immunologic approach may lead to the discovery of the sensitizing ingredient or ingredients in tobacco and thus perhaps to a method for eliminating or destroying the harmful factor.

SUMMARY AND CONCLUSIONS

The studies herein reported were carried out in the main, by means of intradermal tests of the skin with tobacco extracts and with nicotine in cases of thrombo-angitis obliterans.

Six concepts of fundamental immunologic nature form the basis of the hypothesis that some cases of certain diseases of the vascular system (thrombo-angitis obliterans, angina pectoris and coronary disease) clinically long considered to be in some way connected with smoking, are manifestations of hypersensitivity in certain segments of blood vessels to circulating allergens derived from or contained in tobacco.

Concept 1 There is localized and circumscribed fixed specific hypersensitivity, i. e., a hypersensitivity confined to a certain organ or part of an organ may develop.

Concept 2 There is a predilection of certain allergens to sensitize and elicit reactions in certain tissues, i. e., whereas any allergen may sensitize any part, almost all allergens have their favorite point of attack.

Concept 3 Not only sudden and evanescent reactions are elicited when the excitant meets the specifically sensitized shock tissue, but chronic reactions and permanent organic damage are often caused by one or successive shocks resulting from such encounters.

Concept 4 There is an idiosyncrasy, meaning that certain persons react in a manner different from that of the norm, allergens causing reactions in the idiosyncratic person cause no reactions in normal persons. Allergens are thus usually of harmless nature and are not poisons or toxins in the pharmacologic or toxicologic sense.

Concept 5 The vascular system in man seems to be peculiarly susceptible to sensitizations and is thus most frequently the seat of reactions. Examples of this are found in many diseases of the skin. The wheal reaction is, in itself, a demonstration of vascular hypersensitivity.

⁸ Sulzberger, Marion B. Studies in Tobacco Hypersensitivity. I. Comparison Between Reactions to Nicotine and to Denicotinized Tobacco Extract, J Immunol 24 85 (Jan) 1933.

Concept 6 The skin is useful as a test tissue in a great variety of hypersensitivities of internal organs.

The experiments in patients with thrombo-angitis obliterans and in controls have brought to light the following data: Seventy-eight per cent of the patients with thrombo-angitis obliterans tested had positive reactions of the skin to tobacco. 36 per cent of the smokers without thrombo-angitis obliterans and 16 per cent of the nonsmokers gave positive reactions.

The persons afflicted with thrombo-angitis obliterans were not atopic and there were no regularly demonstrable reagins in their sera.

As the positive skin tests in patients with thrombo-angitis obliterans correspond with the clinical evidence incriminating tobacco, these results are regarded as highly suggestive that sensitization of the vascular system to tobacco may play a causal or contributory role in many cases of thrombo-angitis obliterans.

Although tobacco was the principal allergen causing positive reactions of the skin in thrombo-angitis obliterans, other allergens and, notably, inhalants also elicited positive responses.

It is assumed that cases of thrombo-angitis obliterans must exist in which other excitants and not tobacco are the major factors.

That part of the tobacco which elicits the skin reaction of hypersensitivity is coetastable and thermostable and is not destroyed by ultraviolet rays or x-rays in the dosages we employed. It is not nicotine.

Nicotine is of little or no importance in sensitizations to tobacco. If the diseases under discussion are sensitizations to tobacco, nicotine is, in all probability, of little or no importance in their causation.

It is hoped that the new immunologic approach and the employment of animal sensitizations will lead to the experimental reproduction of certain diseases clinically attributable to damage by tobacco. As is well known, all toxicologic attempts to do this have failed.

One of the objects of such experimental studies would be to isolate and eventually, to eliminate the actual sensitizing factor or factors from tobacco.

ABSTRACT OF DISCUSSION

DR. GEORGE MILLER MACKEF, New York: Dr. Sulzberger's instructive, inspiring and conservative article describes his experimental work with tobacco sensitization. He has drawn conclusions some of which are based on definite facts while others are theoretical deductions. All are logical. He has made not a single dogmatic statement. The subject is open for continued investigation. Two important facts in the paper are, first, that in many instances the effects of tobacco are due to allergy to some yet unknown allergen in the plant and not to nicotine as previously believed. Various species may have different allergens, or human reactions to the same allergen may vary. The second fact is that these allergens have an affinity for the circulatory system in various parts of the body. The shock center may be in any layer of the skin or in any organ. Dermatologists are familiar with tobacco dermatitis (eczema venenatum). A continuation of this investigation may show that other types of eczema are caused by tobacco allergy. The paper calls to mind the importance of skin tests in practical work and especially in research. In spite of the enormous amount of work that has already been accomplished, the enormous possibilities of properly conducted skin tests are only beginning to be appreciated. When one is thoroughly acquainted with delayed reactions, intermittent allergy, generalized and fixed areas of sensitization, shock centers, passive transfers and polyallergy and can properly interpret the results obtained, one can obtain valuable information in cases of eczema venenatum, neurodermatitis in infants, children, adolescents and adults, urticaria, dermatophytide and other atopic and allergic con-

ditions of the skin and other organs. I urge that every dermatologist include adequate skin testing in his office practice and that every graduate dermatologic curriculum contain a course that covers this subject comprehensively and in detail.

DR. WILLIAM ALLEN PUSEY, Chicago: I have seen Dr. Sulzberger smoking this afternoon and therefore his conclusions are not open to the skepticism not to say hostility of most of the investigators by nonsmokers. His suggestions are interesting. In the first place he offers a hypothesis—the only one that I know—that is consistent with the known clinical facts concerning the effects of tobacco. His suggestions also are in accord with what is known of localized sensitizations occurring in the skin. For example, the paper this afternoon on fixed drug eruptions presents an illustration of fixed sensitization of blood vessels in the skin producing an inflammatory reaction which when long continued, may result in vascular sclerosis, the same sort of process occurring in blood vessels sensitized to tobacco might produce a sclerosis in certain vessels of the heart or of certain vessels of the legs. Dr. Sulzberger's observations are an illustration of the light that may be thrown by the study of pathologic processes in the skin on similar processes occurring in other parts of the body.

DR. WAITER J. HICHMAN, New York: I was impressed by the criteria and postulates by which Dr. Sulzberger wisely controls himself in reaching his conclusions. I was impressed by his statement that the pet idea of sensitization in the great majority of instances is erroneous that something entering the body of persons who are sensitized to many things may produce the condition called sensitization. More simply stated Dr. Sulzberger's paper can be summed up in the maxim that one man's meat is another man's poison. Dr. Sulzberger is not a confirmed allergist and therefore not a subscriber to the allergy racket. I too think that every man should be his own allergist in every instance.

DR. PAUL A. O'LEARY, Rochester, Minn.: My colleagues Drs. George E. Brown and N. W. Barber studied the influence of cigaret paper rather than tobacco as a factor in the production of occlusive vascular disease. They used weaker dilutions of the paper extract in the skin testing of patients with Buerger's disease, with essentially negative results. The fact that Dr. Sulzberger used a concentrated tobacco extract may account for the high percentage of positive skin tests he obtained. Horton demonstrated in 40 per cent of a group with Buerger's disease a micro-organism which when introduced into animals reproduced occlusive vascular disease. In the Scientific Exhibit there is a demonstration showing that rye bread (ergot) is an etiologic factor in this disease. These three demonstrations suggest that the blood vessels of the individual with occlusive vascular disease may be allergic to tobacco, ergot and bacteria and of course there may be other etiologic allergens that have not as yet been elicited. The allergists no doubt look with favor on the multiple etiologic factor concept of this disease, while to others such a concept is subject to severe criticism. Obliterating endarteritis was formerly thought to be confined to male Jews who smoked cigarets to excess. It is now found about as frequently in male Gentiles, and less frequently in women who do not smoke.

DR. WINSTON U. RUTLEDGE, Louisville, Ky.: Coming from a tobacco state and a tobacco manufacturing center, I have seen many cases of dermatitis due to contact with tobacco. I have treated several men who, when buying the loose leaf developed in some instances generalized erythematous eruptions and others who had maculopapular eruptions involving only the exposed portions of the body and who suffered from these dermatoses only during the tobacco season. I have seen such dermatoses, both in tobacco buyers and in workers in tobacco factories. In such places they frequently develop eruptions and practically the only cure is to get the patient away from tobacco. In my experience patch tests in such cases have been to a large extent negative, and I do not know how to account for their negativity. Dr. Cannon brought to my attention the possibility that the condition might be an arsenical dermatosis because arsenic plays an important part in the growing of tobacco. I also had the idea that perhaps some of these eruptions were fungus disease but I failed to demonstrate a fungus in any instance. I had one patient who did not develop a derm-

titis while working with tobacco in North Carolina, but on two occasions, while burning tobacco in Kentucky, had such an eruption. This example illustrates the statement made by one of the discussers that tobacco from different sections of the country may possess different allergic properties.

DR. MARION B. SUZUKI, New York. I think the application of skin tests in many conditions in which no one has thought of applying them may lead to further knowledge. To know when, where and how to apply these tests what substances to use, what to look for and how to study and evaluate the skin reaction is obviously a part of dermatology. Dr. O'Leary is absolutely right in saying that I did not by any means wish to imply that thromboangitis obliterans is always due to tobacco sensitization. That would be against all the known facts regarding sensitization in general. I believe that many cases may perhaps be accounted for by tobacco but there must be other cases which can be accounted for by other agents. I do not think that the factors Dr. O'Leary mentioned contradict the theory of sensitization of the blood vessels. I have seen cases of erythema nodosum a vascular disease, due to sensitization to bromides, to bacteria and fungi, and to foods. In the cases referred to by Dr. O'Leary there may be a vascular sensitization to bacteria to rye or even to ergot. I realize that the riddle of thromboangitis remains unsolved just as unsolved as that of asthma, hay fever, eczematous dermatitis or drug eruptions. Even when a disease is known to be a sensitization, and the allergen is recognized there remain the questions: Why does this person become sensitized? and Why to this particular substance? and Why does he react with this or that shock tissue and in this or that specific manner? Dr. Highman has frequently discussed these points. Here the neurologic, endocrine constitutional, vasomotor chaos is still without even a nebular hypothesis.

TREATMENT OF CHRONIC HEART DISEASE BY LOWERING THE METABOLIC RATE

THE NECESSITY FOR TOTAL ABLATION OF THE THYROID

HARRY F. FRIEDMAN, M.D.
AND
HERRMAN L. BLUMGART, M.D.
BOSTON

In several previous communications the treatment of chronic intractable heart disease by removal of the thyroid gland in toto was demonstrated as a feasible and effective procedure in patients without clinical or pathologic evidence of thyrotoxicosis.¹ The success of this type of therapy was the logical result of an extended series of observations on the circulation in chronic heart disease, hyperthyroidism and myxedema,²

from which the conclusion had been drawn that by reducing the basal metabolic rate one would lessen the demands on the circulation and relieve the diseased heart of its burden. These considerations were equally applicable to congestive failure and angina pectoris.³ The permanent reduction of the metabolic rate was accomplished by surgical removal of the entire thyroid gland according to the technique developed by Berlin and first performed by him, Dec. 15, 1932. This is the first time that a total ablation of the normal thyroid gland for chronic heart disease of nonthyrogenous origin had ever been performed.^{1b}

Several investigators had in occasional instances performed subtotal thyroidectomy for relief of chronic heart disease because of the obvious benefits this operation had conferred on hearts embarrassed by a state of hyperthyroidism. These cases presented clinical signs or symptoms of thyrotoxicosis and a heightened basal metabolic rate or showed improvement after compound solution of iodine, the gland, however, in some cases appeared normal grossly and microscopically.⁴ It is well known that subtotal thyroidectomy reduces the abnormally high basal metabolic rate of thyrotoxicosis to normal,⁵ there is no evidence in the literature, however, that subtotal thyroidectomy can be relied on to produce a permanently subnormal basal metabolic rate. The previous work failed to justify subtotal thyroidectomy as a valid therapeutic measure for the relief of nonthyrogenous disabling heart disease.

In the first two cases^{1a} that engaged our interest only transient relief was obtained by subtotal thyroidectomy; the period of relief paralleling the curve of decline in the basal metabolic rate. Even though maximal subtotal thyroidectomy was done in these two cases we failed in our primary purpose to reduce permanently the basal metabolic rate. Even if success might occasionally attend subtotal thyroidectomy, it became apparent that nothing but complete removal of every vestige of thyroid tissue would insure a permanent subnormal metabolic rate and clinical improvement.^{1a} Total ablation of the thyroid gland in the treatment of chronic heart disease through the persistent lowering of the basal metabolic rate has now been demonstrated to be effective in over fifty cases at the Beth Israel Hospital.

The desirability of permanently lowering the metabolic rate by means less drastic than surgery presented itself. The possibility of producing this effect by irradiation was therefore considered. As far as we know, the effect of irradiation of the normal thyroid gland of man on the metabolic rate had not previously been investigated.

Röntgen radiation was also employed in two patients in whom maximal subtotal thyroidectomy had been

This study was aided by a grant from the William W. Wellington Memorial Research Fund of Harvard University.

done without benefit. It seemed reasonable to expect that the minute amount of thyroid tissue left after surgery might become hypertrophied and would be more readily influenced by irradiation than an entirely normal gland.

REVIEW OF LITERATURE

Roentgen therapy has been used for many years in the treatment of toxic goiter and a malignant condition of the thyroid. Pfahler and Vastine⁶ reviewed 100 cases of goiter treated by roentgen radiation. These cases were grouped to include 13 cases of simple or colloid goiter, 241 cases of hyperplastic goiter of which 238 were exophthalmic, 118 cases of adenomatous goiter, of which 92 were nontoxic and 26 toxic, 2 cases of nonsuppurative thyroiditis, and 26 cases of carcinoma of the thyroid gland. The roentgen factors employed in giving the treatments to this group of cases were 9 inch spark gap, 5 milliamperes, 6 mm. of aluminum filter and 10 inch target distance, 50 per cent of an erythema skin dose being given through each of four portals directed to the gland. This was repeated in three weeks, from six to eight series of treatments being given. As a result of this treatment hypothyroidism developed in four cases, or 17 per cent. Holmes and Means,⁷ Simpson,⁸ Jenkinson⁹ and Groover and his associates¹⁰ obtained similar results, and Groover likewise reported that hypothyroidism was produced in 13 per cent of his cases. Bowing¹¹ of the Mayo Clinic treated 167 cases of thyroid cancer by radiation alone or radiation and surgery. Two cases of myxedema developed in his series. The development of myxedema in these patients may not have been due to irradiation but may simply represent the incidence of spontaneous myxedema in any representative group of thyrotoxic patients who are followed over a period of time without specific treatment.¹² Ginsburg¹³ reported that he treated 500 goiter patients with radium as much as 6,000 mg. hours being given to the gland in a single dose with no evidence of myxedema. Since our own results in the treatment of toxic goiter were similar to the results obtained by the aforementioned authors we were led to believe that the production of myxedema by irradiation of the normal thyroid would be difficult.

METHODS AND RESULTS

In the treatment of toxic goiter 800 roentgens measured without backscatter directed to the gland (160 roentgens being given every other day for five days), is usually sufficient to lower the metabolic rate. Occasionally, this dose must be repeated. The factors used in our first group of four cases were the same as those employed in patients with toxic goiter as shown in the accompanying table. The total roentgens however amounted to twice and sometimes three times the usual dosage. This was considerably more than that used by Pfahler and Vastine.⁶ The metabolic rates of these patients, as will be shown, were not influenced. Two of the four patients had had a subtotal thyroidec-

tomy, with nine tenths or even more of the thyroid gland removed before roentgen therapy was instituted. As already noted irradiation had no effect on these two cases, indicating that it would be difficult or impossible to produce permanent myxedema by irradiation with the doses given.

In view of these results even larger dosage was given. Our experience in the treatment of cancer of the larynx led us to believe that we might be able to influence the normal thyroid by the Coutard method, which consists in giving heavily filtered roentgen radiation over a longer period of irradiation hours. Accordingly, two patients were treated with the Coutard¹⁴ dosage applied to the gland through one portal, 4,000 roentgens measured without backscatter being adminis-

Roentgen Therapy in Six Cases

Case	Number of Treatments	Duration of Therapy, Days	Roentgen Units
1	18	17	1,500
2	18	14	1,500
3	11	14	900
4	10	11	1,000
5	19	11	4,000
6	11	10	4,000
Total therapy for toxic goiter	5	10	800

Roentgen factors used:
Cases 1-4: 60 kilovolts, 4 milliamperes, 6 mm. of copper, 1 mm. of aluminum filter.
Cases 5-6: Same except for filter, 2 mm. of copper, 1 mm. of aluminum.

tered as shown in the table. In cases 5 and 6, treated by this method the typical epidermitis and the epithelitis of the trachea developed which lasted for a period of two weeks following the last treatment. No significant change in their metabolic rates was noted however over a period of three months after the last treatment.

The basal metabolic rate measurements were made by means of a Collins-Benedict Roth machine and were always done in duplicate.

REPORT OF CASES

CASE 1—Hypertensive heart disease, coronary disease and congestive failure of two and one-half years duration.

I. B., a man aged 45, admitted to the Beth Israel Hospital, Sept. 15, 1932, had a history of dyspnea on exertion of two years duration. On one occasion, soon after the onset of his illness, he suffered one severe attack of precordial pain lasting ten minutes. He was first admitted to the Beth Israel Hospital two years previously and at that time showed signs of pulmonary congestion, ascites, and a vital capacity of 2,000 cc. An electrocardiogram showed inverted T waves in leads 1 and 2 and prolonged auriculoventricular conduction. The blood pressure was 176 systolic, 100 diastolic, his basal metabolic rate was plus 3. He improved, was discharged, and did fairly well until eight months before the present admission, when he was again forced to bed. In spite of remaining in bed most of the time he became progressively worse.

On admission he showed severe dyspnea, orthopnea of necks, and deep cyanosis of the lips and mucous membranes. The heart was moderately enlarged, there was a gallop rhythm, and the rate was 100. The blood pressure was 180 systolic, 110 diastolic. There were signs of congestion over both lung fields posteriorly and fluid at the left base. Ascites and moderate pitting edema of the legs, hands and forearms were evident. The basal metabolic rates September 9 and October 4, were plus 9 and plus 7 per cent of normal. October 17, a maximal subtotal thyroidectomy was performed, in which more than nine tenths of the normal gland was removed.¹⁴ The

basal metabolic rates on November 1, 2, 3, 4, 8, 12 and 18 were minus 12, minus 6, minus 18, minus 15, minus 12, minus 14 and minus 12, respectively. During this period the patient showed clinical improvement. The basal metabolic rate then began to rise gradually, reaching plus 2 December 3. From this time on, clinical improvement was not sustained and the patient again showed an increase in the signs of congestive failure. An unsuccessful attempt was made subsequently to remove the remaining fragments of thyroid tissue by surgical intervention. Dense connective tissue adhesions obscured the anatomic landmarks and made any surgery hazardous.

Roentgen treatment was instituted, December 27, and continued to Feb 9, 1933. During the period of treatment the metabolic rate at intervals of days was minus 2, minus 11, minus 7, minus 8, minus 14, minus 3 and minus 14 per cent. On July 13 and 15, approximately five months after treatment, the metabolic rates were plus 8 and plus 6 per cent.

During the past few months the patient has continued to show evidence of congestive failure with complete inactivity and he is now confined to bed rest in a hospital for chronic diseases.

CASE 2—General arteriosclerosis arteriosclerotic heart disease, auricular fibrillation and congestive heart failure of two and one-half years' duration

H B, a man aged 59, was admitted to the Beth Israel Hospital, Nov 1, 1932 for the fifth time in two and a half years, because of edema of the legs, pain in the right upper quadrant and shortness of breath. His last discharge from the hospital was six months before this admission, at which time the diagnoses were arteriosclerotic heart disease, auricular fibrillation, congestive failure and Paget's disease. He had been confined to bed practically the entire time and the signs and symptoms of congestive failure had become progressively more pronounced.

Physical examination showed cyanosis, orthopnea, grossly irregular heart action and an enlarged heart. Both lungs were congested, and the liver was enlarged and tender. Moderately deep pitting edema was present over both lower legs, feet and the sacrum. The blood pressure was 140 systolic 70 diastolic. The seven foot roentgenogram of the chest showed the transverse cardiac diameter to be 22.1 cm, the internal chest diameter, 29.4 cm. Electrocardiographic tracings showed auricular fibrillation and bundle branch block.

November 23, a maximal subtotal thyroidectomy was performed, more than nine tenths of the gland being removed. The basal metabolic rate fell from an average of minus 4 to minus 15 per cent, with concomitant clinical improvement. Following this, however, he again began to gain edema, and the metabolic rate rose to the preoperative level.

Roentgen treatment was begun December 27, and continued until March 1, 1933. During the course of the treatment the metabolic rates progressively fell from minus 4 to minus 21 per cent but quickly returned to previous levels shortly after the last treatment. March 3, 6, 15 and 23 the metabolic rates were plus 1, plus 13, plus 24 and plus 9 per cent. On July 29, approximately five months after the termination of treatment, the basal metabolic rate was minus 8 per cent of normal. The patient continued to show evidence of congestive failure. During the past two months the signs and symptoms of circulatory failure have increased so that at the present time he is confined to bed with general anasarca.

CASE 3—Angina pectoris, of four years' duration

O H, a man, aged 68, was admitted, Feb 21 1933, complaining of attacks of substernal pain during the previous four years. The pain was severe, was viselike, would often radiate to the left arm, was precipitated by exertion, and was immediately relieved by rest or glyceryl trinitrate. These attacks gradually increased in severity and frequency and in the previous two months appeared even on rest. There was no significant dyspnea, no cough and no edema. One year before admission he was told that he had diabetes and three months before he developed a mild left hemiplegia from which he had almost entirely recovered.

Physical examination showed moderately advanced arteriosclerosis of the retinal and peripheral vessels. The thyroid gland was of normal size. The chest was somewhat emphysematous, the lungs were clear. The heart was moderately enlarged, the sounds were of fair quality and regular. There

were no murmurs. There was no edema. The blood pressure was 160 systolic, 90 diastolic. A seven foot roentgenogram showed moderate cardiac enlargement and calcification of the aorta. The electrocardiogram showed inverted T waves in leads 1 and 2.

Because of the patient's age, the history of a recent cerebral accident, and the marked coronary sclerosis, it was felt that he was a poor surgical risk for total ablation of the thyroid gland and roentgen therapy was instituted in the hope of accomplishing a lowering of the metabolic rate by this means.

Basal metabolic rates, February 23, March 1 and 2, 1933 were minus 16, minus 10 and minus 22 per cent. Roentgen treatment over the thyroid gland was instituted, March 6, and continued until March 20. Thirteen treatments were given at daily intervals, seven directed to the left and six to the right aspect of the neck. Each treatment consisted in giving 200 kilovolts 4 milliamperes, through a filter of 0.5 mm of copper and 1 mm of aluminum from a distance of 20 inches for a period of twenty minutes, with a total dosage of 2,080 roentgens. The basal metabolic rate, March 13 was minus 13 per cent. July 15 and 16, plus 12 and 0 per cent of normal. The patient continued to have frequent attacks of angina pectoris, and after being studied at the Boston Dispensary for several months and given every available treatment, he has shown no improvement.

CASE 4—Rheumatic heart disease, mitral stenosis and insufficiency, auricular fibrillation and congestive heart failure of two and one-half years' duration

S M, a man, aged 33, admitted to the Beth Israel Hospital, Jan 30, 1933 complained of dyspnea, orthopnea and weakness of two and a half years' duration. He was first admitted to the hospital, May 5, 1930, complaining of cough, tightness in the chest, dyspnea, palpitation and blood-streaked sputum of five weeks' duration. Physical examination showed cyanosis, orthopnea, enlarged heart and the signs of mitral stenosis and insufficiency. During the two years following his first admission his activity became increasingly limited, and signs of congestive failure gradually progressed.

Physical examination at the time of the present admission revealed moderate cyanosis of the lips, dullness at both lung bases, marked cardiac enlargement, and grossly irregular heart sounds. The liver was enlarged four fingerbreadths below the costal margin. There was no pitting edema. The blood pressure was 185 systolic and 90 diastolic. A seven foot roentgenogram of the chest showed a transverse cardiac diameter of 25.4 cm and an internal chest diameter of 27.6 cm.

Roentgen treatments were given from February 3 until February 14, a total of 1,660 roentgens being directed to the thyroid gland. The basal metabolic rates, February 1 and 8, were plus 6 and plus 1 per cent respectively. The metabolic rate on February 15, after treatment, was plus 3 per cent.

During his stay in the hospital the patient's condition failed to improve. He was discharged, February 18, and died suddenly one week after discharge.

CASE 5—Rheumatic heart disease, mitral stenosis, auricular fibrillation and congestive failure (No improvement after irradiation of the thyroid gland, definite improvement after subsequent total ablation of the thyroid)

S B, a woman aged 46, admitted to the Beth Israel Hospital April 24, 1933, had had rheumatic fever twenty-five years before at which time she was told that she had heart trouble. Since that time she had suffered from palpitation and dyspnea on exertion and on rare occasions she had had slight swelling of the ankles after being up and about for a considerable period of time. During the twelve months previous to her present admission, dyspnea, orthopnea and palpitation had become more pronounced.

When she was first admitted to the hospital, Aug 12, 1932, physical examination revealed slight dyspnea, some dullness at the right base, cardiac enlargement, grossly irregular heart action, and a rough diastolic murmur at the apex. In the epigastrium there was a mass, apparently the liver, which was slightly tender. There was no pitting edema of the extremities. During her stay she developed a transient hemiplegia, which cleared up after a few days. She was discharged, but readmitted, April 24, 1933, for roentgen irradiation of the thyroid gland.

Roentgen treatments were given from May 3 to May 24 1933, the Coutard method of irradiation being employed, directed through one portal over the thyroid gland, with a total dosage of 4000 roentgens. The metabolic rates before treatment on April 25, 26, 27 and 29 were plus 1, plus 14, plus 8 and plus 11 per cent of normal, respectively. The basal metabolism was plus 30 per cent, May 13, plus 7 per cent, June 1, and plus 1 per cent, August 3.

During the three months following the institution of treatment her condition remained approximately unchanged. The patient was apparently comfortable as long as she stayed in bed, but she had practically no capacity to be on her feet and developed symptoms on the slightest exertion. For this reason she was readmitted to the hospital and, August 9, total ablation of the thyroid gland was performed. In the course of the operation, numerous delicate adhesions were found between the capsule of the gland and the surrounding tissue. The gland weighed 115 Gm. On section the cut surface was reddish brown, and numerous fibrous striations were seen. Microscopic examination of the tissue revealed alveoli well filled with pink-staining colloid. These alveoli were lined by flattened cuboidal epithelium. The outlines of the alveoli were regular and round and did not reveal any intolding or papillary projections. There was some increase in the amount of connective tissue surrounding the alveoli. Lymphocytic foci were evident. All stages of degeneration were seen. In one area there was a small group of cells composed of vacuolated cytoplasm with large vesicular nuclei. The diagnosis was a normal thyroid.

The patient made an uneventful recovery after operation and showed conspicuous improvement. Palpitation disappeared and she became less orthopneic. Two weeks after operation she was permitted out of bed and noted that her breathing was considerably easier with mild exertion. Two months after operation clinical improvement continued. She was up and about without evidence of dyspnea. There was no sign of congestive failure. The basal metabolic rate had been permanently lowered and she had begun to show mild signs of myxedema.

CASE 6—Rheumatic heart disease, mitral and aortic stenosis, auricular fibrillation and congestive failure of three years duration.

M. B., a woman, aged 38, was admitted, April 23 1933, for the third time in three years because of rheumatic heart disease, mitral and aortic stenosis and insufficiency, auricular fibrillation, congestive failure and diabetes. She had had repeated attacks of congestive failure in the past and she was first told nine years before that she had heart disease. During the past three years there had been marked limitation of her reserve, with dyspnea on moderate exertion. A few days before admission she complained of "hot flashes," dry cough and palpitation, but there was no shortness of breath or edema.

Physical examination showed a cherry-red cyanosis of the face and lips, cardiac enlargement, the typical murmurs of mitral stenosis and aortic insufficiency, grossly irregular heart sounds, a blood pressure of 140 systolic, 70 diastolic, nontender enlargement of the liver to three fingerbreadths below the costal margin, and no edema. A seven foot roentgenogram of the chest showed the transverse diameter of the heart 17.9 cm., and the internal chest diameter 26.1 cm.

The patient refused operation and, accordingly, roentgen irradiation of the thyroid gland was instituted May 3 and continued to May 24, the Coutard method being employed one portal over the thyroid gland, with a total dosage of 4000 roentgens. Seven tests of the basal metabolic rate from March 31 to April 28 averaged plus 2.8 per cent. The basal metabolic rates on May 29 and June 1 were minus 7 and plus 8 per cent, respectively.

During the past few months the patient has shown no significant change in her cardiac condition.

COMMENT

Total surgical ablation of the thyroid gland, which has now been performed at the Beth Israel Hospital in more than fifty cases presenting congestive failure or angina pectoris, produces persistent lowering of the basal metabolic rate and definite clinical improvement. In the hope that irradiation of the normal thyroid

gland might be useful as a substitute for surgery or as an adjunct to subtotal thyroidectomy, the foregoing study was made. Cases 1 and 2 were the first cases in which operation was done (same as cases 1 and 2 of the first communication^{1a}). At this time the importance of removing every bit of thyroid tissue was not appreciated, nor had the technic been evolved by Berlin^{1b}. In these initial operations all thyroid tissue was removed with the exception of the minute amounts at the upper poles and in the tracheo esophageal sulci. Such maximal subtotal thyroidectomy produced only temporary lowering of the metabolic rate and temporary clinical improvement. After success attended the first complete ablation of the thyroid (case 3 of first communication^{1a}), a subsequent attempt was made to remove the remaining fragments of tissue in case 1, in which there had been a relapse to the preoperative clinical condition. Dense adhesions were encountered, which made identification of thyroid fragments impossible. It was felt that any surgical dissection would have been extremely dangerous because of the difficulty of identification and consequent likelihood of injury to the parathyroid glands or recurrent laryngeal nerves. Since the clinical condition of both patients was unimproved, heavy dosages of roentgen radiation were employed but without effect.

The effects of roentgen irradiation were also studied in four other cases in which operation was contra-indicated. These cases failed to show any clinical improvement or lowering of the metabolic rate. Operation later became feasible in one case 4. Complete ablation of the thyroid gland was done under gas oxygen anesthesia. Microscopic examination of the gland showed for the most part normal thyroid tissue, indicating that, in order to destroy the function of the thyroid, prohibitive dosage would be necessary. Following total ablation of the thyroid gland, the basal metabolic rate has been persistently low, and the patient has shown conspicuous clinical improvement.

These observations lead to the conclusion that little can be expected from roentgen radiation as a substitute for surgery or as an adjunct to subtotal thyroidectomy in the treatment of chronic disabling heart disease. At the present time nothing but the complete removal of every vestige of visible thyroid tissue by surgical means will guarantee the desired persistent lowering of the metabolic rate and the consequent clinical improvement.

SUMMARY

1 Roentgen irradiation of the normal thyroid gland, used alone and also as an adjunct to maximal subtotal thyroidectomy, failed to produce any appreciable persistent lowering of the basal metabolic rate in six patients with chronic heart disease.

2 In one case, previously reported, in which a maximal subtotal thyroidectomy had been performed both roentgen irradiation and a subsequent surgical attempt to remove the remaining fragments of the thyroid tissue were unsuccessful, and the clinical condition was not improved.

3 One patient whose condition remained the same in spite of massive irradiation showed conspicuous improvement coincident with the reduction in the basal metabolic rate when the entire thyroid gland was removed according to the technic previously described by Berlin.

4 The failure of others and of ourselves to benefit patients by subtotal thyroidectomy, our unsuccessful attempt to remove residual fragments at a subsequent

operation, and the ineffectiveness of roentgen irradiation on the remaining tissue emphasize the therapeutic importance of removing the entire gland at the time of the first operation. Ample confirmation for this conclusion was obtained by our subsequent experience in some fifty cases of angina pectoris or congestive failure in all of which the basal metabolic rate remained low after total ablation of the thyroid gland and in practically all of which the clinical improvement has been conspicuous.

PHILADELPHIA

Within the past decade a widespread interest has been shown in a variety of substances that have been recommended for surgical anesthesia. It can be said as a commonplace that, when so many substances are used for anesthesia, not one is ideal from the standpoint of the patient, the surgeon and the anesthetist. This paper is a report of our experiences with still another substance which while not new has only recently been suggested by Leake and his associates as an agent for surgical anesthesia.

In 1930, Leake and Chen¹ predicted from a consideration of the chemopharmacologic properties of diethyl ether and of ethylene that compounds combining the chemical characteristics of each would be interesting general anesthetic agents. Such a compound would be divinyl ether (fig 1). Studies made by these investigators and by Knoefel, Guedel and Leake² seemed to bear out their prediction. Their observations indicated that divinyl ether showed great promise for qualifying as an ideal general anesthetic.

In 1931, Rugh and Major³ reported the successful preparation of pure divinyl ether and described its properties.

Pure divinyl ether is a clear, colorless liquid with a specific gravity of 0.77 at 20 C, and a boiling point of 28.3 C. It is as explosive and inflammable as diethyl ether and is more volatile. The divinyl ether that has been prepared for anesthesia has added to it a small amount of absolute alcohol to prevent too rapid evaporation, and an inhibiting substance to prevent decomposition. It is this mixture which we have used in our studies. Divinyl ether polymerizes on exposure to air and light and in the presence of acid decomposes to form aldehydes, one of which is formaldehyde, which is formed in very minute amounts.

Divinyl ether has a not unpleasant ethereal odor and when pure, is not as pungent or as irritating as

diethyl ether. However when decomposed or polymerized, it has according to Leake, a "stinging odor and causes definite local irritation." In a more recent paper, Leake, Knoefel and Guedel⁴ reported that its physiologic actions were less severe than those of diethyl ether. They found no significant pathologic effect when it was administered without anoxemia. Gelfan and Bell⁵ administered the anesthetic in three instances to human patients and on the basis of their observations suggested that it was worthy of a clinical trial and evaluation.

The material with which the experiments reported in this paper were conducted was supplied to us by the Laboratory of Pure Research of Merck & Co., Rahway, N. J. All the material was tested for decomposition and polymerization before its use.

We have studied the comparative effect of divinyl and diethyl ether on the blood pressure and respiration, and the concentrations of these substances in jugular vein blood at the onset of the third and fourth stages of anesthesia in dogs, and similarly in man, except that the blood was removed from a vein in the antecubital fossa during complete surgical anesthesia.

The anesthetic was administered to the dogs by inhalation through several loose layers of gauze or after tracheal cannulization and to the human patients either by open drop inhalation or in conjunction with nitrous oxide and oxygen. It will be possible in this paper to review only briefly the work we have done.

CLINICAL STUDIES

The anesthetic was not administered to the human patient until our laboratory studies were completed and we had satisfied ourselves that it could be safely administered.

The studies in the human cases were conducted in the Hospital of the University of Pennsylvania. In all 461 patients were anesthetized. To the first fifty patients the anesthetic was administered by one of us while the rest of the patients were anesthetized by the regular nurse anesthetists of the hospital.

The open drop method was used in about 90 per cent of the series, since we believed that with so highly volatile an anesthetic this method offered the greatest safety until we had become more experienced with the use of divinyl ether in the human patient. The method was as follows. Several loose layers of gauze were placed over the patient's face after the eyes had been covered with a piece of moistened gauze. The anesthetic was dropped slowly from a dropping bottle while the anesthetist talked to the patient and carefully observed his reactions. To the others it was administered in conjunction with nitrous oxide and oxygen through one of two makes of apparatus, the divinyl ether being placed in the ether reservoir. When given by this method, only a very small amount should be used, since rapid bubbling of the oxygen through the divinyl ether results in too great concentration of the anesthetic in the inspired gas.

The ages of the patients varied from 5 months to 82 years. The anesthetic was so well tolerated by children that we have used it extensively in this group for general surgical and otologic operations. Fifteen of the patients were under 2 years of age and twelve were over 60. The weights of the patients varied from a few

pounds to 274 pounds (121 Kg.) and the physical make-up was of the variety encountered in any surgical clinic.

The conditions for which anesthesia was induced were extremely varied. It was used for operations for the duodenum, brain tumor and middle ear disease, thyroidectomy, gastrostomy, gastro-enterostomy, appendectomy, herniorrhaphy, mastectomy, and operations on the soft parts and bony skeleton. With the single exception of two operations for cholecystectomy, however, the anesthetic was not used for operations on the biliary tract.

It is difficult, as can be attested by those of us who have been anesthetized with this and other anesthetic agents, to describe the effect of divinyl ether in terms of the classic stages of anesthesia. The first stage is, as a rule, extremely short—so short in fact that consciousness is often completely lost after a few inhalations. Thus, the picture of analgesia without loss of consciousness, which is seen in the more commonly used inhalation anesthetics, is only rarely observed. The laryngeal reflexes, which are often irritated when diethyl ether is used, are rarely observed with divinyl ether.

Guedel⁶ has pointed out that there is a light stage of surgical anesthesia which affords the surgeon as much ease and comfort in operating as the state of

of divinyl ether for the induction for an appendectomy, the period from beginning the anesthetic to the beginning of the operation being three and a half minutes. The individual variation may be shown in a second patient aged 23 who had good relaxation in two minutes and in whom only 60 cc of divinyl ether was used.

over a twenty-five minute period. For minor surgical operations the time for induction varied as a rule from twenty seconds to two minutes.

The time of anesthesia varied from ten minutes to two hours and fifty-one minutes. We occasionally observed considerable mucus in patients who had been administered the anesthetic for only a short period—a condition that was considerably more frequent in the dog. This occurred even though atropine sulphate was administered previous to operation. When mucus was present it disappeared immediately after recovery from the anesthetic.

Even in the patients who had excessive mucus there was no increased tendency to postoperative respiratory complications. The extraordinary absence of respiratory complications in 461 anesthetizations may in part be explained by the care in selection of cases and the unusual care inevitable in the first tests with a new anesthetic. Much as it is to be hoped for it will scarcely be surprising if this record is not maintained in the future should divinyl ether come into general use.

The muscular relaxation was good. It was as good as that obtained with diethyl ether and was sufficient for the most extensive laparotomy or for orthopedic manipulations.

The respiration was, as a rule, quiet except when there was a considerable accumulation of mucus. Gen-

TABLE 2—Concentration of Divinyl Ether in Blood (Intercostal Fossa) of the Human Being During Surgical Anesthesia

erally the respiratory rate became slower during the period of surgical anesthesia. In only nine patients was cyanosis observed such as often occurs when nitrous oxide and oxygen are pushed to obtain good surgical relaxation. One of these patients was a child aged 15 months in whom the anesthesia was being used for an ophthalmic operation. The child became cyanotic and cessation of respiration rapidly followed. The pulse remained of excellent quality and after a very short

Fig. 1—Chemical composition of divinyl ether

deepest third stage anesthesia." This is a period of quietude and tranquillity which affords efficient relaxation and at the same time a maximum of safety to the patient. It is characterized by surgical anesthesia at a time when the eyeballs are oscillating rhythmically. A patient in such a condition is, according to Guedel, in the ideal stage of surgical anesthesia, and we have noted that with divinyl ether it was relatively easy to maintain this stage throughout the operation and at the same time to have efficient relaxation. The continuous movement of the eyeballs at first disturbed us, but subsequent experience proved that it was a state for which to strive rather than at which to be alarmed. It disappears in deep third stage anesthesia.

In only 2 per cent of the patients did we observe real excitement, and this was of very short duration. The rapidity of induction prevents in even the most nervous patient any real or prolonged stage of excitement.

The time from the beginning of the administration of the anesthetic to surgical anesthesia varied, of course with the type of operation. For relaxation sufficient for a laparotomy, about three and a half minutes was necessary. For extra-abdominal lesions the time was less than this. Several illustrations may be helpful in showing its effectiveness. A man, aged 21, required 14 cc

period of artificial respiration the color became good and normal respiration was resumed. This observation was in accord with our experience in the dog, in which it was usually possible to resuscitate the animal rapidly after cessation of respiration.

Records of the blood pressure were kept during 100 operations. In eight patients there was a fall of from 10 to 19 per cent from the preanesthetic level, while in five patients there was a drop of 20 per cent or more. In the remaining patients the fall was less than 10 per cent. The anesthetic was used in patients with a variety of cardiac diseases, including advanced myocardial damage, without any untoward effect.

The amount of divinyl ether necessary for maintenance of anesthesia was, on the average, about 2 cc per minute. At times it was less than this and occasionally it exceeded this amount. The tendency of the anesthetists was at first to use more than was necessary, basing the rate of the drop on experience with the administration of diethyl ether. It is advisable for anesthetists to begin with minor surgical cases until experience is gained with the anesthetic.

Fig 2—Upper strip, divinyl ether. A light anesthesia (blood pressure 160/80). B surgical anesthesia (blood pressure 145/60). C terminal stage (blood pressure fifteen seconds before respiratory failure 155/45). The duration of anesthesia was sixty five minutes. The persistence of the pulse after respiratory failure was three minutes and fifteen seconds. Lower strip, diethyl ether. A light anesthesia (blood pressure 170/120). B surgical anesthesia (blood pressure 160/110). C terminal stage (blood pressure fifteen seconds before respiratory failure 190/130). The duration of the anesthesia was forty two minutes. The persistence of the pulse after respiratory failure was three minutes.

Recovery was unusually rapid. It was often possible, after the anesthetist had had experience with the anesthetic, to have the patient speaking at the time of introduction of the last skin suture. Recovery was, as a rule, smooth and was only rarely accompanied by any excitement, which was very probably due to the rapidity with which the patient's faculties for rationalization returned. The usual period for recovery to the stage of answering questions rationally after operations with a duration of from twenty to forty minutes was from thirty seconds to five minutes. In a patient with a breast carcinoma the duration of the operation was one hour and twenty-two minutes, and the time from complete withdrawal of the anesthetic to recovery was twenty seconds. When preliminary narcotics were used, the period of recovery was sometimes longer. Only in patients with pin-point pupils from the administration of morphine prior to anesthetization did the recovery period exceed five minutes.

Vomiting, including simple ejection of mucus, during the recovery from the anesthetic occurred in 95 per cent of the patients. This, as a rule, consisted in the emesis of mucus on one or two occasions. In only one instance did we believe that exaggerated vomiting was related to the anesthetic. A number of patients who had only recently eaten were anesthetized because of surgical emergencies, and the infrequency of vomiting in this group was striking. In patients in whom postoperative oral feeding was not contraindicated, the rapid return of appetite for food was also striking.

The urine was examined repeatedly before and for several days after operation in nearly one half of the cases and in no instance did we obtain any evidence of renal irritation. Even after repeated anesthetization in a patient whose urine previous to operation was normal, no evidences of renal damage or irritation could be found. The anesthetic was used in a number of urologic operations. In patients in whom prolonged or repeated anesthesia might have resulted in liver injury, no evidence of injury could be demonstrated from determinations of the serum bilirubin.

The anesthetic was administered as often as five times to the same patient. It was administered to about thirty-seven patients who previously had had other anesthetics, and in every instance they expressed the opinion that the induction and recovery with divinyl ether was more pleasant than with the anesthetics that had previously been administered to them.

PHYSIOLOGIC STUDIES

In the experiments on both the dog and the monkey no preliminary medication was administered. Third stage anesthesia was more rapidly induced and recovery was more rapid than with diethyl ether. Although considerable accumulation of mucus occurred in the dog, this was not on the whole as great as that observed with diethyl ether. There was, however, a great deal of individual variation in the dogs.

Another example of individual peculiarity was the occasional presence of running motions, usually noted in dogs in which anesthesia was difficult to maintain, although the other signs of complete surgical anesthesia were present. The behavior of the monkey under divinyl ether was more like that of the human being. In the monkey, oscillation of the eyeballs during third stage anesthesia was frequently observed.

In the monkey divinyl ether and chloroform caused no accumulation of mucus, while it frequently followed the administration of diethyl ether. Recovery following three hours of divinyl ether anesthesia took place in from three to six minutes; in fact, the one monkey that was anesthetized for six hours was on its feet and eating a banana within six minutes.

In dogs the concentration of divinyl ether in the blood from the jugular vein at the time of disappear-

7 Since this paper was written the number of patients subjected to divinyl ether anesthesia has exceeded 2,000. Four patients have come to autopsy within five days after operation. In two of these evidence of a central lobular necrosis of the liver was found. We are briefly reporting these two cases through the kindness of Dr. Dean Lewis of the Johns Hopkins Hospital.

CASE 1—H. R., a man aged 54. Diagnosis: carcinoma of the stomach. Operation: partial resection of the stomach, anterior gastroenterostomy, and entero-enterostomy. Duration of anesthesia: two hours and forty minutes. Amount of anesthetic used: 350 cc. Died in his sleep on the third day after operation. No untoward symptoms between operation and death.

CASE 2—H. G., a woman aged 23. Diagnosis: appendicitis. Operation: exploratory laparotomy, appendectomy, and exploration of pelvis and upper abdomen. Duration of anesthesia: one hour and thirty-nine minutes. Amount of anesthetic used: 275 cc. Convalescence uneventful for forty-eight hours. She then became drowsy and unresponsive. On the fourth day she became very restless, the pulse rose to 130 and the respirations to 33. On the fifth day she would not respond; the respirations dropped to 12 and the pulse rose to 160 before death.

ance of the corneal reflex averaged 28 mg per hundred cubic centimeters of blood (table 1), while when diethyl ether was administered under identical conditions the concentration of this substance averaged 116 mg per hundred cubic centimeters of blood.

These results would indicate that in the dog the anesthetic potency of divinyl ether was approximately four times that of diethyl ether, which figures are somewhat

TABLE 3—Effect of Divinyl Ether, Diethyl Ether and Chloroform on the Liver of Well Fed and of Starved Dogs

greater than those reported by Knoefel, Guddel and Lenke,² who estimated the alveolar concentration of the anesthetics.

The mean concentration of divinyl ether in the blood of the external jugular vein of the dog at the time of cessation of respiration was found to average 68 mg per hundred cubic centimeters of blood. In our studies on the dog the concentration of diethyl ether under comparable conditions at the point of respiratory failure was found to average 155 mg per hundred cubic centimeters of blood. In both of these groups the animals were under anesthesia for three hours before the anesthetic was pushed to the point of respiratory failure.

On the basis of these data it would appear that the actual difference in milligrams per hundred cubic centimeters of the blood concentration between the anesthetic and the lethal dose of divinyl and diethyl ether is approximately the same. It should be admitted, however, that in inexperienced hands it would be easier to pass from the anesthetic to the lethal concentration of divinyl ether. The use of margin of safety ratios in this connection would be, we believe, somewhat misleading. In the hands of the careful anesthetist, divinyl ether has a satisfactory margin of safety.

In the human patients (table 2) the results showed an average concentration of divinyl ether in peripheral venous blood, in third stage anesthesia of 18 mg per hundred cubic centimeters of blood (nine determinations), as against 132 mg in a single determination under diethyl ether.

We observed no significant differences in the effects of divinyl and diethyl ether on the blood pressure and respiration of the dog (fig 2). In neither were any sharp variations in blood pressure noted as long as good surgical anesthesia was maintained. The fall in the blood pressure from the level present during light anes-

thesia to the level existing during surgical anesthesia was approximately the same for both diethyl and divinyl ether. In human cases in which precipitate falls in the blood pressure occurred the fall could in every instance be ascribed to some other factor associated with the operation.

As from diethyl ether, death from divinyl ether is due to respiratory failure, the heart continuing to contract for some time after cessation of respiration (fig 2). Since recovery from divinyl ether anesthesia is rapid, artificial respiration usually will rapidly restore an animal whose respiration has ceased.

PATHOLOGIC STUDIES

The effect of divinyl ether on various tissues was studied in seventy-nine dogs and nineteen monkeys (*Macacus rhesus*) under several experimental conditions. Forty-six dogs and ten monkeys were studied under similar conditions after the administration of diethyl ether or chloroform. In this work we had the assistance of Drs. Walsh, Quereau and Wing.

The conditions under which the experiments were performed with the three anesthetics were varied as to the duration of the anesthesia, the number of anesthetizations, the nutritional state of the animal and, with divinyl ether alone, after complete obstruction of the extrahepatic bile ducts.

Specimens of the different organs were taken, as a rule, on the third day following anesthetization, since it was found that when tissue change occurred it could be best demonstrated at that time. The only significant change was found in the liver, so that our report is confined to this organ. Biopsies of the liver were performed under each of the experimental conditions prior to beginning the experiment to serve as controls.

Divinyl ether may induce liver necrosis in the dog. When liver damage followed divinyl ether anesthesia, the histologic picture was that of a central lobular necrosis. To this extent it resembled the liver necrosis of chloroform anesthesia. However, under identical experimental conditions the liver change that followed divinyl ether anesthesia was in general less marked than after chloroform. In contrast to the dog, liver damage

TABLE 4—Effect of Divinyl Ether, Diethyl Ether, and Chloroform on the Liver of Well Fed and of Starved Monkeys

Nutritional State	Anesthetic	Periods of Anesthesia	Number of Monkeys	Number with Liver Necrosis
Well fed	Divinyl ether	1 period of 3 hrs	3	0
		2 periods of 3 hrs	13	0
		1 period of 6 hr	1	0
	Diethyl ether	1 period of 3 hrs	1	0
		1 period of 3 hrs	3	0
Starved (2 days)	Chloroform	1 period of 3 hrs	2	0
	Divinyl ether	1 period of 3 hrs	4	0
	Diethyl ether	1 period of 3 hrs	2	0

did not occur in the monkey following divinyl ether anesthesia under any of the experimental conditions that were used. In neither animal did diethyl ether produce liver necrosis.

The results of the experiments on dogs are summarized in table 3. In a group of sixty-nine well fed normal dogs anesthetized for various periods with divinyl ether, thirteen were found to have developed liver necrosis. Necrosis was not found after one hour of anesthesia. It occurred, however, in two (10 per cent) of twenty-one animals anesthetized for one two-hour period, and in eight (30 per cent) of twenty-seven

dogs anesthetized for one three-hour period. The remaining three instances of liver necrosis followed four two-hour periods of anesthesia in seven dogs. The interval between anesthetizations for the latter group was four days.

The duration of the divinyl ether anesthesia was thus found to be a definite factor in the production of liver

Fig 3—Necrosis in the liver of the dog induced by chloroform. The inner two thirds of the several lobules shown are necrotic. The cells bordering the necrotic areas contain large fat droplets. Reduced from a photomicrograph with a magnification of 75 diameters.

necrosis in the dog. The critical period in this animal was found to lie between two and three hours.

In the control groups following comparable periods of anesthesia, chloroform anesthesia resulted in liver necrosis in two of five dogs after one hour of anesthesia, and in five of six dogs which received it for two hours and in both of the dogs receiving three hours of chloroform (fig 3). Diethyl ether did not cause necrosis.

Of the five dogs deprived of food for three days prior and two days subsequent to a three-hour period of divinyl ether anesthesia, two developed liver necrosis (fig 4). When under similar nutritional conditions divinyl ether was administered to two dogs for two hours on both the third and the fourth day, liver necrosis was found in one animal. In dogs, necrosis following chloroform invariably occurred under these conditions, while it was never observed following diethyl ether anesthesia.

The necrosis that followed divinyl ether anesthesia in dogs whose food had been withheld was decidedly more extensive than that found in the dogs which were well fed. The importance of the nutritional state in the occurrence and severity of the liver necrosis is well illustrated in the dogs that were anesthetized for two two-hour periods. In the well fed animals liver necrosis was not observed in the four dogs so treated, while, in the two that were starved, liver necrosis was found in one instance.

Two weeks after ligation of the extrahepatic bile ducts and cholecystectomy, three dogs were anesthetized with divinyl ether for one hour, during which time we performed a biopsy of the liver. The his-

tologic picture was not found to be significantly altered three days later. Thus, in the group in which liver necrosis was most feared, none was found.

Of the well fed monkeys given divinyl ether, three were anesthetized for one three-hour period, thirteen for two three-hour periods on alternate days, and one for six hours continuously. None of these showed necrosis of the liver. It is noteworthy that, of three monkeys anesthetized for three hours with chloroform, not one gave any evidence of liver damage (table 4).

When deprived of food for two days prior to anesthetization, two monkeys, following one three-hour period of divinyl ether anesthesia, failed again to show liver necrosis. But two monkeys similarly deprived of food and anesthetized with chloroform for three hours developed liver necrosis, demonstrating that typical necrosis may occur in the liver of the monkey. Diethyl ether anesthesia failed to produce liver necrosis under either of these conditions.

These experiments demonstrate the importance of the nutritional state and the species difference in considering the toxicity of an anesthetic. It may be said that, in respect to its toxicity for the liver in dogs, divinyl ether holds a position intermediate between chloroform and diethyl ether. In monkeys it resembles diethyl ether in this respect.

SUMMARY

We may thus far sum up our experience with divinyl ether by stating that from the standpoint of induction, maintenance and recovery the anesthetic is satisfactory. It affords rapid surgical anesthesia with

Fig 4—Necrosis in the liver of the fasting dog induced by divinyl ether. This kind of necrosis is very similar to that shown in figure 3. Reduced from a photomicrograph with a magnification of 75 diameters.

a minimum amount of the anesthetic, even maintenance, good relaxation and rapid recovery. No untoward effects have been observed on the blood pressure or respiration. The very low incidence of excitement or postanesthetic vomiting and of respiratory complications in our series is noteworthy.

The anesthetic concentration in the blood necessary for surgical anesthesia in dog or man is low, and the

lethal concentration in the dog is nearly two and one-half times the anesthetic concentration. The absolute difference between the anesthetic and the lethal concentrations in the dog for divinyl and diethyl ether is about the same. The anesthetic should be, however, carefully administered, since the lethal concentration of divinyl ether in the dog is only about one-half the anesthetic concentration of diethyl ether. The circulation is well maintained for a time after cessation of respiration.

In the human being we have encountered no untoward effects on the liver or kidneys but we have been careful to avoid its use in patients who were being operated on for disease of the biliary tract. The fact that in the dog it produces under certain conditions liver necrosis is not reason for undue alarm. Chloroform, which causes liver degeneration more easily and more extensively in the dog is more feared for its effect on the heart than on the liver. Furthermore, divinyl ether failed to produce liver necrosis in the monkey under any of the conditions imposed on it.

The anesthetic should be very useful in operations in which rapid induction and recovery with a minimum of after-effects are desirable. Its exact position in relation to the other general anesthetics now being used will have to await a more extensive clinical experience.

ABSTRACT OF DISCUSSION

DR. RALPH M. WATERS, Madison Wis. To have a new drug introduced with a study of some 500 cases before a clinical report is made of it is a rare thing in therapeutics in general. The authors have compared the drug to ether as to induction and recovery. It seems to me that that is not a very interesting thing about a new drug, unless it can be compared with nitrous oxide as to induction and recovery because I feel that nitrous oxide should be the criterion of present agents for induction and recovery. The authors have admitted liver necrosis in dogs. They have not found it in human beings. Liver necrosis has been one of the fears about the old agents and makes one worry a bit perhaps. Let me use what little time I have to tell about my experiences. My associates and I had a supply of the drug furnished us by Dr. Major of the Merck Laboratories Inc. in 1931 and we observed it early in 1932. We found not only these running movements at that time that the authors have mentioned but much more severe muscular activity which could almost be looked on as convulsive in type. We felt that the drug with which we were working must be a different drug from that with which Drs. Lerke, Knoefel and Guedel had worked and, therefore, dropped it. This spring, since the authors were to present a paper here, I was asked to observe the drug which they are using now. The drug was checked by sending some of the lot which was sent to me back to Dr. Rydman for verification of its identity. We find similar results with this drug to the ones that we had in 1932. That is in a certain percentage of dogs with which we have worked we have seen muscular phenomena that were not satisfactory as an accompaniment of anesthesia. In certain cases apparently we could not eliminate these muscular activities even by pushing the drug. Several dogs in the early part of the induction ran into some sort of circulatory disturbance which I find hard to describe but which came on suddenly early in the induction, resulting in the death of the dogs with the cessation of the heart action almost synchronous with the cessation of respiration. Dr. Meek has observed with the electrocardiograph some of these experiences and I hope that he may be able to give his opinion about the effect on the circulatory system, which I am not capable of discussing. From what little I have seen of the drug either I have mishandled it very severely or else the drug has some qualities that I think would not be well to introduce at this time into anesthesia for ordinary practical purposes.

DR. HENRY S. RYDMAN, Philadelphia. This anesthetic was sent to me by the manufacturers about two months ago at the suggestion of Dr. Rydman. Not having at hand the immediate facilities for animal experimentation in the laboratory I accepted the complete report of Dr. Rydman and his associates on his work at the University of Pennsylvania. To date I have attempted its use only in a series of ten patients. I have noticed a comparatively quiet induction with little excitement as compared to ethyl ether. Production of mucus was present in each case but not to the extent to provide annoyance. In every case there was produced an obstruction to respiration which persisted for varying lengths of time. This obstruction was interpreted as a laryngeal spasm because it was not relieved by the induction of artificial airways, nor was the type of phonation that which is caused by obstruction elsewhere in the respiratory passages. I also observed, as the authors mentioned, a wide range in the dosage required. This varied from 75 cc. for fourteen minutes of anesthesia in one patient to the other extreme of 75 cc. producing satisfactory anesthesia for forty-five minutes in another patient. By the ordinary clinical methods of observation of cardiac action, I could observe no deviation from the normal; no electrocardiograms were taken. There was a negligible variation in blood pressure. One experience I was unable to interpret. A woman, aged 25, an excellent physical risk was a subject for a simple bilateral salpingo-oophorectomy. After an induction of three minutes' duration I interpreted the anesthetic plane to be the middle stratum of the surgical stage. The corneal reflex had disappeared a very short time before, which coincided with previous observations that the corneal reflex with this agent disappears early. Oscillation of the eyeballs was still present. The color of the patient was normal, with no clinical signs of anoxemia. The circulatory status of the patient was excellent when suddenly there appeared a state of severe generalized convulsions during which, of course there was practically no tidal respiration whatever. After about a minute and a half from the onset of these convulsions her color began to grow dusky and then cyanotic in rapidly increasing degrees. The lungs were then gently inflated with 100 per cent oxygen which rapidly restored her color and in another moment or two the convulsions subsided. Ethyl ether was immediately substituted as the anesthetic agent and the operation was begun and brought to a successful conclusion devoid of any further complications.

DR. WALTER MECK, Madison Wis. I hesitate to say anything that will detract from a paper so well worked up as that of the authors which has back of it so much experience. My study was with some of Dr. Waters' animals, particularly in regard to the heart. In one case I found a heart block appearing certainly before the animal was at a surgical stage of anesthesia. In a second animal there was no heart block but there was considerable widening of the QRS complex and a split R. That would mean ordinarily that there had been some myocardial damage. A third dog showed the disappearance of heart beats simultaneously with cessation of respiration. The number of animal experiments is somewhat limited. There are only six or seven animals on which I have the straight cardiac study throughout. I may mention another case in which after the anesthesia, a stormy period was finally passed through and the heart then remained normal for a long time. The electrocardiographic results do not seem to be due to the showers of extrasystoles seen in chloroform anesthesia but an entirely different phenomenon an effect either directly on the heart muscle or, of course possibly through the vagus. It is not entirely clear which mechanism is involved. It might be said that the anesthetic had merely been crowded to the toxic stages. At least three of these animals, however, had not passed out of those curious running movements which were found so common in the dog before heart disturbances appeared. It must be realized, of course, that dogs are dogs and people are people, and this new anesthetic might not be very safe for the heart of the dog and still have no objectionable properties for man. I recognize this contingency, although I feel the danger of general cardiac involvements at the present time.

DR. CHAUNCEY D. LRAKE, San Francisco. It is gratifying to know from the studies reported by the authors that the predictions made for divinyl oxide have some reality in fact. I

think the discussion and the presentation of this paper are interesting from the standpoint of oxygen want. The majority of the experiments were performed with the drop method. I think the observations made by Dr. Waters and Dr. Meek on dogs were also made under the drop method. In this method it is necessary during the period of induction to use a much higher concentration of the anesthetic agent than is needed actually for anesthesia. That high concentration throws out the oxygen. I think that many of the experiences that have been described are due more to anoxemia than to a toxic factor in divinyl oxide if the divinyl oxide used was pure. In my own experimental studies in this agent, which were very extensive, I was early led to adopt a method of administration that precluded the possibility of anoxemia. Under those circumstances I found no untoward effects whatever as long as the material was pure. Divinyl oxide is manufactured from a chlorinated ether. Although it is stated that it is free from the presence of chlorinated ether, I think some samples nevertheless, may still retain traces of this agent. The chlorinated ethers are not at all anesthetic; they are very toxic. I have found it may be that the cardiac and liver effects described are due to traces of chlorinated ethers in the presence of anoxemia. I should like to ask the authors whether they noted clinically a degree of abdominal relaxation before intercostal paralysis occurred. This was a factor that I considered from the experimental standpoint, as being favorable for human anesthesia. I found in my own studies no liver kidney, cardiac, lung or any other significant pathologic injury whatever on repeated administrations at half hour intervals daily for as many as thirty days in dogs provided there was no anoxemia. The extensive mucous secretion to which reference was made is due, I think, to local irritation, which may again be caused by the possible presence of minute traces of impurities in the compound. Such impurities, Dr. Major informed me, may be formaldehyde or formic acid, which are extremely irritative in very small concentrations not detectable chemically. Any trace of any impurity, therefore, in the compound might be expected to induce deleterious effects, particularly if the agent is administered with anoxemia. It is my opinion that material that is to be used for human beings should be as the authors have said, first tried on experimental animals.

DR. RALPH M. WATERS, Madison Wis. I should like to correct a misunderstanding on Dr. Leike's part. Several of these animals under the electrocardiograph were anesthetized with pure oxygen as the vehicle.

DR. HIRSH E. ESSER, Rochester Minn. My observations of this anesthetic have been very limited. My experiments have been on rabbits and dogs. With rabbits I have found that induction and recovery are very rapid, but my experience has not been the same with the dog. Some dogs seem to go under easily and some do so with a great deal of difficulty. My experience with one dog would answer the description that Dr. Ruth gave of one of his patients. On another I used three bottles, 75 cc in each bottle and the dog was still struggling and it was necessary to switch to diethyl ether in order to get the animal anesthetized. Regarding recovery, my experience has been variable. Some dogs seem to come out quite rapidly and others take longer. I took dogs that were to be operated on, and put some under the divinyl ether and some under ethyl ether. The recovery period went from five to twenty-five minutes with the divinyl ether and many times it was not longer with the ethyl ether. There is one thing I noted as I gave the anesthetic by the open drop method and that was the irritating effect on the eyes of some of the assistants. One individual seemed particularly sensitive to this drug.

DR. JOHN S. LUM, Rochester Minn. I have used this agent only in operations for radical amputation of the breast, so that operative conditions might be as nearly similar as possible in each case. I have tried it with morphine and without, and with and without a barbiturate. I observed unilateral dilatation of the pupil of two patients which may have no relation at all to the drug. I observed a certain amount of rigidity of the jaw, a certain stertor that I was unable to avoid except in one case in which I finally got the jaw well forward and then the airway apparently was free. I have not yet discovered the proper method of administration of this particular agent unless it is that I have not provided a clear airway.

The consignment sent to the clinic was tested by Dr. Osterberg and found to be pure according to the tests for purity. In both rabbits and man anesthetized with this drug the same type of dispenser was noted.

DR. I. S. RABIN, Philadelphia. The discussion has unfortunately been limited to those who have had a very short experience with divinyl ether. My associates and I will be very happy if a year from now, when the various workers have had a wider experience with this substance, they will again report their results. In regard to liver necrosis, which Dr. Waters mentioned it should be recalled that the anesthetic was used in dogs in which two weeks previously an obstruction of the common bile duct had been produced. This is the type of lesion that in man at least would make one most fearful of extensive liver necrosis with an anesthetic that may produce injury to the liver. In none of the animals so treated did liver necrosis occur. Dr. Leike has brought out the factor of anoxemia and it is probable that certain of the running motions which we observed were associated with anoxemia. We do not believe that the liver necrosis was due to this. The circulatory phenomena which Dr. Waters and Dr. Meek described we have not experienced although we have made no electrocardiographic studies. In the dog and in the monkey, repeated sections were made of the heart muscle and there was no evidence of myocardial change in animals that had been subjected to long periods of anesthesia. It has been our feeling that there was no laryngospasm connected with this anesthetic. We have repeatedly introduced a bronchoscope during anesthetization with divinyl ether and had no difficulty getting through into the trachea of these animals. We observed no convulsions during divinyl ether anesthesia but I know that convulsions may occur even during diethyl ether anesthesia. The degree of abdominal relaxation in man is good—as good as that seen with diethyl ether. It would be interesting if Dr. Lundv and Dr. Essex would induce the anesthesia in Dr. Mann's anesthesia chamber by the method he uses for the induction of diethyl ether anesthesia. The experiences that we have had with this anesthetic in nearly 600 anesthetizations were on the whole very satisfactory. We at times observed the peculiar freezing of the jaw as stated in the paper, and also in man we had at times considerable mucus and some stridor. It has been our feeling that the latter was associated with a falling backward of the tongue rather than with laryngospasm because when a soft rubber airway was provided the difficulty immediately disappeared. If this is due to laryngospasm, it should not disappear. We presented this report because it seemed to us that this anesthetic agent might be useful in surgical practice. We wish to stress that final decision will have to await a much more extensive clinical experience.

The Use of the Senses—The lemon tint of pernicious anemia, not always readily distinguished from the more sallow tint of gastric malignancy, a disease which it may simulate in many other ways, is none the less characteristic. In gastric cancer it is more likely that there will be evidence of loss of weight, with the so called cachectic appearance, and a slightly bluish nose is a frequent feature. The brick-red facies of polycythemia sometimes simulating rude health at a first glance, but often with a tinge of blueness or purple to modify opinion, is quickly confirmed by turning down the deep-red eyelid just as we do in looking for the conjunctival pallor of anemia. The watery eye, the blotchy face and the reddish venous nose of alcoholism, sometimes with tremulous lips and tongue, may give the clue to a correct interpretation of digestive or nervous symptoms. Acne rosacea may likewise prompt a diagnostic of gastritis. The slightly drooping lids and wrinkled forehead of tabes, and the parkinsonian mask of paralysis agitans or past encephalitis with its flat unsmiling, sad, uncomfortable lack of expression (quite different from the puffy impassivity of myxedema), are strongly diagnostic. The dark greenish brown of chronic obstructive jaundice and the dirty muddy-brown pallor of uremia, whether due to chronic interstitial nephritis in a young man or to prostatic obstruction in an old are other examples of diagnostic color change.—Ryle, J. A. *The Training and Use of the Senses in Clinical Work*, *Guy's Hosp Gaz* 47:421 (Oct 28) 1933.

INFILTRATION VERSUS SPINAL ANESTHESIA IN OBSTETRICS AND GYNECOLOGY

J. P. GREENHILL, M.D.
CHICAGO

Obstetricians and gynecologists have only recently begun to use local anesthesia to any great extent. However, surgeons long ago recognized that it was advisable to avoid the use of inhalation anesthetics when operating on individuals with serious medical complications such as respiratory infections, heart trouble, kidney disease, high blood pressure and diabetes. Therefore, local anesthesia in some form was used for these cases. Later it became apparent that if local anesthesia was less hazardous for seriously ill patients it was also safer for individuals whose general physical condition was good.

DISADVANTAGES OF GENERAL ANESTHESIA

Briefly, the disadvantages of inhalation anesthesia are as follows:

- 1 No general anesthetic is perfectly safe. Therefore there is a definite though slight mortality. In a study of 148 deaths following gynecologic operations Bartlett and Simmons¹ found that eighteen, or 12.3 per cent, occurred on the operating table as a result of the ether. Of the eighteen patients who died only four were poor risks, but the rest were satisfactory subjects for a general anesthetic. The incidence of deaths from ether in 10,325 abdominal operations was 0.15 per cent or one death in 738 cases. Thornton² maintains that there is an increased incidence of deaths under anesthetics. He found the mortality rate to be 0.19 per cent for all general anesthetics. Kaye³ reported a series of 107 deaths which occurred during anesthesia, of which ninety-nine occurred under general and eight under local anesthesia. Of course, far more patients are operated on under general than under local anesthesia, but Rollison⁴ encountered six deaths during 6,062 general and no deaths in a series of 1,981 local anesthetics.

- 2 There is a distinct risk of pneumonia and other pulmonary complications.

- 3 Acidosis and alkalosis may result from prolonged anesthesia.

- 4 Shock may follow a long anesthesia.

- 5 Dehydration is common after prolonged anesthesia.

- 6 There is lowered resistance of the peritoneum to infection.

- 7 There is a toxic effect on the liver and other vital organs which makes inhalation anesthesia especially bad for women who have toxemias of pregnancy, cardiovascular disease, diabetes, goiter, hypertension and pulmonary disorders.

- 8 There are frequent gastro-intestinal disturbances after operation, especially vomiting, distention and "gas pains."

- 9 Under general anesthesia there is a tendency to mishandle tissues, and this may lead to complications such as thrombosis and embolism.

DISADVANTAGES OF SPINAL ANESTHESIA

Most surgeons who employ local anesthesia use some form of spinal injection. This method has the following disadvantages:

- 1 There is a definite mortality. Cooke⁵ says that spinal anesthesia "is apparently as judged by mortality statistics more dangerous than general anesthesia on the whole." Bower, Clark and Burns⁶ make the following statements: "Spinal anesthesia is responsible for more deaths than any other anesthetic in proportion to the number administered. Undoubtedly many deaths have occurred from the (spinal) anesthetic that have been attributed to other causes. Up to the present time there is no known method of absolutely preventing deaths from spinal anesthesia, but artificial respiration offers the best means of combating respiratory embarrassment and fall in arterial pressure." M. E. Babcock⁷ collected 215,000 cases of spinal anesthesia and in this series there were seventy-five deaths, or one in 2,867 cases. Through questionnaires, he received information that forty-six hospitals had had ninety-one deaths on the table and eleven after operation, all attributable to spinal anesthesia. Eighteen of these hospitals listed 15,652 spinal anesthetics with forty deaths on the table (one in 400 spinal anesthetics). Rapoport⁸ reports a series of 500 spinal anesthetics with nineteen pneumonias and seven deaths. Sise⁹ collected reports of fourteen deaths which occurred under 1,900 spinal anesthetics in Greater Boston during 1928. Bortone¹⁰ in eighty-five New Jersey hospitals found one death for every 1,628 general and one fatality for every 311 spinal anesthetics.

Generally the deaths due to spinal anesthesia occur shortly after the injection of the anesthetic. The fatalities are usually attributed to respiratory paralysis, to the position in which the patient is placed after the injection to a fall in blood pressure or to circulatory changes. However deaths may occur many days after the injection and still be due to this form of anesthesia, as may be proved by a study of the central nervous system.

- 2 The incidence of pulmonary complications is at least just as high as after inhalation anesthesia. In fact, Brown and Debenham¹¹ found that pulmonary complications, especially atelectasis, occurred 4.29 times more commonly after spinal (subarachnoid) anesthesia than after inhalation anesthesia, in spite of the fact that more "bad risk" patients were operated on under general anesthesia. The reasons for this are as follows: First, spinal anesthesia definitely inhibits the depth and force of respiratory movements, not only during the operation itself but also for some time afterward. It is these respiratory movements that tend to rid the tracheobronchial tree of foreign matter or secretions. Second, the normal viscosity of the secretions of the tracheobronchial tree appears to be increased, hence it is more tenacious after spinal anesthesia. Third, the patient tends to remain quiet for a few hours after an operation performed under spinal anesthesia, hence there is a greater possibility for the material in the tracheobronchial tree to obstruct a bronchus with the subsequent development of atelectasis. Arnheim and

Mage¹² report that postoperative pneumonia occurred in 8 per cent of their 120 cases in which nupercaine spinal anesthesia was used. In the 338 cases reported by McKittrick, McClure and Sweet¹¹ there were eighteen cases of postoperative pneumonia, but since there were sixteen additional complications of the respiratory system the incidence of these complications was 10 per cent. They accounted for 40 per cent of all the complications in this series. The mortality rate in the group of postoperative pneumonias was 46 per cent. Since the incidence of pulmonary complications is at least as high as if not higher than after general anesthesia, spinal anesthesia should not be chosen in the hope of preventing these complications.

3 There is a definite toxic effect on the spinal cord and the spinal nerve roots which is manifested both clinically and pathologically.¹⁴ Davis, Haven, Givens and Emmett¹⁵ injected the most commonly used spinal anesthetics into the dural sacs of dogs and observed the following changes: a varying degree of inflammatory reaction in the leptomeninges, changes in the ganglion cells of the gray matter of the cord, swelling and fragmentation of the axis cylinders, and signs of degenerative changes in the fiber tracts of the cord. Myelitis and meningitis may result from an infection carried in with the needle or solution, but they may also occur in the presence of a generalized infection that tends to localize at the site of the lumbar puncture. There may be early and temporary effects such as headaches and mild paralysis of the oculomotor and abducens nerve. The late effects, which may appear months and years afterward, are paralysis of the sphincter ani and incontinence, spastic paralysis and paraplegia.

4 There is frequently a pronounced fall in blood pressure, which may be accompanied by vomiting, restlessness, pallor, cold sweat, weak pulse, shallow respirations and sometimes unconsciousness. In 10.8 per cent of the series reported by McKittrick, McClure and Sweet,¹¹ the fall in systolic blood pressure during the operation was 50 per cent or more of the preoperative level. In 25 per cent of these cases the blood pressure did not return to the preoperative level for at least twenty hours after the patients returned to their wards.

5 Nausea and vomiting occur in many cases during the course of the operation, and this may prove troublesome.

6 Headaches both temporary and persistent frequently occur after operation.

7 The uterus may fail to relax when this becomes necessary. In more than half the cases spinal anesthesia retards labor, necessitating operative intervention. This is most likely due to abolition of the sensory phase of the sensory-motor reflex, which normally brings the voluntary muscles into action.

8 Pregnant women are especially susceptible to complications after spinal anesthesia. This is the opinion of such authorities as Winter,¹⁶ Konrad,¹⁷ Pankow,¹⁸ Heim,¹⁹ Babcock²⁰ and others. De Lee²⁰ knows of

seventeen deaths in obstetrics from spinal anesthesia. Brindeau²¹ encountered two deaths due to spinal anesthesia in 102 cesarean sections, and Lull²² says "Of the fourteen cases (of cesarean section) done under spinal anesthesia two patients died before the operation was started." M. E. Babcock²³ also reports four deaths while women were undergoing abdominal delivery. Aside from the increased risk, it is technically difficult to administer spinal anesthesia to a woman at or near full term because of the impossibility of properly flexing the trunk.

9 After the drug has been injected into the spinal canal it is beyond control and, if alarming symptoms appear, the cause cannot be removed.

10 Special knowledge is required both for the injection of the drug and for the recognition and treatment of complications.

11 The method fails in at least 5 to 10 per cent of all cases. In Arnheim and Mage's²⁴ series, supplementary inhalation anesthesia had to be employed in 32.8 per cent of the cases. Deaver and Eckels²⁴ report that in their series of 2,302 cases additional anesthesia was required in as high as 32.3 per cent. In nearly all cases in which supplementary anesthesia is necessary, a general anesthetic is chosen. As McKittrick, McClure and Sweet¹¹ emphasize serious harm may result if proper care is not exercised in the administration of a general anesthetic when the field of operation is already anesthetized.

12 In some instances the danger of spinal anesthesia is greater than that of the operation itself.

13 Spinal anesthesia is hazardous in women with anemia and cardiac decompensation.

14 It cannot be used in cases of shock due to intra-abdominal hemorrhage, abruptio placentae or other causes.

15 Only a small proportion of physicians would be willing to submit to spinal anesthesia. As Bevan²⁵ points out, "the application, therefore, of the Golden Rule should limit spinal anesthesia to a narrow field."

16 Not only is the technic of spinal anesthesia not standardized but also there is no unity of opinion concerning the proper drug to be used. There are advocates of procaine hydrochloride, novocain (a brand of procaine hydrochloride), spinocaine (a non-Council accepted brand of procaine hydrochloride with strychnine sulphate), neocaine (a French brand of procaine hydrochloride), tutocain, nupercaine, stovaine (amylocaine hydrochloride B. P.), pantocain, apothesine and other substances, and this array indicates that no one drug is entirely satisfactory.

DISADVANTAGES OF INFILTRATION ANESTHESIA

1 Infiltration anesthesia cannot be used if the site at which the solution must be injected is infected or inflamed.

2 If it is known or suspected that many peritoneal adhesions will be encountered, infiltration anesthesia should not be attempted. Nevertheless in many cases this type of anesthesia may be used for most of the operation, aided by a short general anesthetic when the adhesions are being dealt with.

3 This form of anesthesia should not be attempted in a woman who is exceedingly high strung and has in almost morbid fear when she is told that her operation will be performed under local anesthesia. Fortunately there are only a few women of this type. Their number can still further be reduced by properly preparing patients for this form of anesthesia. After all, local anesthesia is a relatively new procedure, and patients believe that they will see their operation performed, that they will hear all that goes on in the operating room and that they will experience much pain. A proper preparatory talk on the part of the operator is essential. The patient should be promised that her eyes will be covered so she will not see anything around her, that the conversation she will hear will not be gruesome or disagreeable, that the rattle of instruments and pans will be reduced to a minimum and above all that, if she feels much pain and so desires it, a general anesthetic will be administered to her. The operator should live up to his promises all the way through the operation or the patient may lose confidence, become hysterical and demand a general anesthetic. The chain of local anesthesia consists of the operator, his assistants (including physicians and nurses), the patient and the local anesthetic. The most important link in the chain is the operator himself. He must first of all convince himself that local anesthesia is the safest and simplest of all anesthetics. He must learn the simple technique and, above all, must be willing to sacrifice the extra time and physical and mental effort that operations performed under local anesthesia demand.

ADVANTAGES OF DIRECT INFILTRATION ANESTHESIA

1 There is practically no mortality due to this method. The number of fatalities reported in the literature as having occurred after infiltration anesthesia is extremely small and in most instances the drug responsible for these deaths was cocaine. As far as I know, this drug is never used for obstetric or gynecologic operations at the present time.

2 There are no pulmonary complications directly attributable to this procedure. It is of special importance in the delivery of women who have pulmonary disorders such as tuberculosis, bronchitis, asthma and influenza. It is also an advantage in the delivery of women who have eclampsia and preeclampsia, because these patients are particularly susceptible to pneumonia. This type of anesthesia is most helpful during the seasons of the year when grip and pneumonia are prevalent. One of the chief reasons for the absence of pulmonary complications is the fact that the lungs are well aerated not only during delivery or operation but also afterward. Frey²⁶ reports a series of 281 cesarean sections performed under direct infiltration anesthesia without the occurrence of pneumonia in a single instance, whereas in the seventy-two cases in his series in which general anesthesia was used, five patients developed pneumonia. I have performed 111 cervical cesarean sections under direct infiltration anesthesia without the occurrence of postoperative pneumonia or a fatality. However, two women in my series of cesarean sections developed pneumonia after ether anesthesia and both recovered.

3 There are no local or general complications. There are only three possible sources of trouble and fortunately I have never seen any. A needle may break during an injection, especially if an old or rusty needle

is used. To prevent this, only good needles should be employed. Furthermore, since a needle practically always breaks near the hub the needle should never be inserted its full length so that, should it break off, it can readily be extracted. The second possible source of trouble is the injection of the solution directly into a vein. This might cause disturbing symptoms, which, fortunately, last only a short time. To avoid this, one should, before injecting the solution into any area, always pull up on the plunger of the syringe to see whether any blood is drawn into the barrel of the syringe. If blood is seen, a new area must be selected for the injection. Furthermore, the needle should be kept in constant slow motion while the solution is being injected. The third possible complication is an idiosyncrasy against the drug used. I always employ procaine hydrochloride (novocain). In Mayer's²⁷ analysis of forty-three unreported deaths from local anesthesia, cocaine was responsible for twenty-six fatalities but procaine hydrochloride even though it is used far more frequently than any other local anesthetic, caused only one (possibly two) of the fatalities.

4 The technique is simple and may be employed in a home as well as in a hospital.

5 There is no bad effect on such vital organs as the liver, lungs, heart, circulatory apparatus and central nervous system.

6 No special knowledge is required. The physician himself carries out the procedure and he is therefore not dependent on another individual.

7 No special after-care is required, as is necessary after general and spinal anesthesia.

8 There is a striking reduction of bleeding in the field of operation so that the amount of blood lost is almost negligible.

9 There is no interference with the action of the uterus, of the abdominal wall, or of respiration.

10 Gastro-intestinal symptoms after operation are uncommon.

11 Patients may take liquids and carbohydrates before during and after the operation.

12 Infiltration anesthesia enables one to operate on very sick persons and on old ones.

13 There is seldom need to hurry through an operation, hence more attention can be paid to proper suturing.

14 The tissues must be handled gently, this is advantageous to the patient.

15 There is less wound infection, owing to diminished local trauma and to the fact that the patient's general resistance has not been lowered.

16 Electrical apparatus such as the cautery may be used without fear of an explosion.

17 It permits the performance of minor operations in a physician's office.

18 It eliminates the fear of an operation in some cases.

INDICATIONS FOR LOCAL ANESTHESIA

The notion that local anesthesia should be used only when there is some contraindication to the employment of general anesthesia is still too prevalent. Therefore individuals with cardiac or renal disease, pulmonary complications, severe diabetes, toxic goiter, marked anemia and those well advanced in years are the ones chiefly selected as candidates for local anesthesia. In obstetrics, the women especially chosen for this type of anesthesia are those who have pulmonary complica-

tions or toxemia of pregnancy, notably preeclampsia or eclampsia. In gynecology it is the 'poor risk' patients who form the subjects. However, local anesthesia is being used more and more by some obstetricians and gynecologists, and it may not be a wild prophesy to suggest that the time will come when instead of saying 'Local anesthesia should be used when general anesthesia is contraindicated' one will say 'Inhalation or spinal anesthesia should be employed only when infiltration anesthesia cannot be used'.

Obstetric operations that may be performed under infiltration anesthesia are the following:

- 1 Dilation and curettment for incomplete abortion, therapeutic abortion, hydatidiform mole, missed abortion and other reasons
- 2 Spontaneous delivery
- 3 Episiotomy and repair
- 4 Repair of childbirth lacerations, both recent and old
- 5 Low forceps delivery
- 6 Cesarean section, classic or cervical type, before or during active labor
- 7 Porro's hysterectomy
- 8 Anterior vaginal hysterotomy (vaginal cesarean section)
- 9 Sterilization, abdominal and vaginal

Gynecologic operations that may readily be done under infiltration anesthesia are the following:

- A Vaginal
 - 1 Removal of Bartholin gland
 - 2 Vulvectomy
 - 3 Dilation and curettment
 - 4 Anterior colporrhaphy
 - 5 Posterior colporrhaphy
 - 6 Repair of third degree laceration
 - 7 Operations on the cervix such as amputation or the Sturmdorf operation
 - 8 The Watkins-Wertheim transposition operation
 - 9 Repair of vesicovaginal or rectovaginal fistula
 - 10 Vaginal hysterectomy
- B Abdominal
 - 1 Salpingectomy and oophorectomy
 - 2 Supracervical hysterectomy
 - 3 Defundation
 - 4 Suspension of the uterus
 - 5 Myomectomy
 - 6 Ectopic pregnancy
 - 7 Appendectomy
 - 8 Sympathectomy
 - 9 Exploratory laparotomy

TECHNIC

Needless to say the surgical preparation of the vagina or of the abdomen is the same as that when inhalation anesthesia is employed. Usually my obstetric patients are given a hypodermic of one-fourth grain (16 mg) of morphine and $\frac{1}{200}$ grain (0.3 mg) of scopolamine about fifteen minutes before the infiltration of the local anesthetic is begun. Thus far I have never seen any harm to the mother or to the baby from this procedure. My impression is that the babies which seem to show the evil effects of morphine are those delivered from two to four hours after their mothers have received the drug. The babies born within an hour of the injection are rarely affected. The patients who are to have gynecologic operations are given one-fourth grain of morphine and $\frac{1}{200}$ grain of scopolamine seventy-five minutes before and one-sixth grain (0.01 Gm) of morphine and $\frac{1}{200}$ grain of scopolamine thirty minutes before the operation. The narcosis due to morphine persists for a variable length of time after the operation is ended, and this usually ensures sleep or at least comfort for some time after the patient's return to bed.

The patient should be made as comfortable as possible during the operation. Hence abundant pillows should be placed on the operating table, especially under the back and around the shoulders where braces are usually applied. The knees should be tied down gently, but the arms need only be placed in a loose sling alongside the body. Generally a trained anesthetist or a nurse sits at the head of the patient, fans her face if she feels warm, places cracked ice in her mouth if she is thirsty and encourages her from time to time if this is necessary. The operator likewise should talk to the patient occasionally unless the patient tends to become drowsy from the morphine. In this case no undue noise should be made during the remainder of the operation.

For the local anesthetic, 0.5 per cent procaine hydrochloride is used although 0.25 per cent is almost as effective. To this solution after sterilization 2 drops of 1:1,000 epinephrine is added for each ounce. The amount of solution made up will depend on the type of operation to be performed. For small vaginal operations such as episiotomy, repair of lacerations, dilation and curettment, plastic operations and low forceps operations, not more than 4 ounces (120 cc) is usually necessary. For laparotomies including hysterectomy and cesarean section, between 6 and 10 ounces (180 and 300 cc) must be used. It is advisable to make up a little more solution than is usually necessary.

The description of the technic used for the various vaginal and abdominal operations may be found in my previous papers²⁸ on this subject and those by Gellhorn,²⁹ one of the pioneers in this field, and by Falls³⁰

CONCLUSIONS

The foregoing comparison between inhalation, spinal and infiltration anesthesia tends to show that infiltration anesthesia is by far the simplest and safest of all types and spinal anesthesia the least satisfactory. It is not urged that infiltration anesthesia be used as a routine for all obstetric and gynecologic operations, but a plea is made for the more widespread use of this form of anesthesia. Increased use of infiltration anesthesia will certainly reduce the incidence of postpartum and postoperative mortality and morbidity.

185 North Wabash Avenue

ABSTRACT OF DISCUSSION

DR JOSEPH B. DE LEE, Chicago. Dr J. Clarence Webster was the first to do a cesarean section in Chicago under local anesthesia. At the Lying-in Hospital we have done eight or nine hundred cesarean sections under local anesthesia. Not one patient has died from the anesthetic. I insist in our hospital that the solution be made by the supervising nurse in the operating room so that there is a direct carrying of the medicine by the nurse to the operating table. When nurses and doctors have the direct care of their patients, they are more particular about details. We have never had pneumonia, bronchitis or edema of the lungs following anesthesia unless the patient was operated on under local anesthesia because of the existence of a bronchitis or a pneumonia. There is an inherent objection to an operation without an anesthetic, inherited from the past. Dr Greenhill referred to the fact that some people, fearing general anesthesia will permit operation under local anesthesia.

- 29 Gellhorn, George. Local and Spinal Anesthesia in Gynecology and Obstetrics. J. A. M. A. 61: 1354 (Oct. 11) 1913. Surg. Gynec. & Obst. 45: 105 (July) 1927. 51: 484 (Oct.) 1930. Am. J. Obst. & Gynec. 23: 908 (June) 1932.
- 30 Falls F. H. Am. J. Obst. & Gynec. 20: 310 (Sept.) 1930.

but this is the exception. One method that I used to overcome prejudice against local anesthesia was to let the women read affidavits signed before a notary, written by women who had had local anesthesia, a day or two before the operation, so they could talk them over with their friends, and then I would introduce a woman who had been operated on under local anesthesia. Another method was the use of music to get the woman's mind off the operation. It gave them a new slant on the situation. That they could listen to music during an operation was a new idea and did more to win the women over to local anesthesia than listening to the music itself. A great many women did not like the music, as it irritated them. About 50 per cent of the women enjoyed it, and curiously they liked high class music, they did not like jazz or orchestras but chamber music best. I found that Kreisler's Vienna caprice was the most popular of all. Now the radio is available, and since the music in the room annoys me when I operate, I have ear-pieces for the patient. The idea of music in operations is not new. I have a picture of a savage woman in the heart of Africa having a baby while her women friends are sitting around thumping on tom toms. I don't know whether they are thumping on the tom toms to drive away the evil spirits or to get her mind off her troubles. Other difficulties come in the operation itself. The doctor must inject his personality into his work. There is no better opportunity than in local anesthesia. One who gets the patient's confidence can accomplish a great deal. Talking during an operation is bad asepsis, one can spit through the mouthpiece and infect the wound. But it is good to encourage the patient with one's voice and one should cover the mouth with an extra two or three layers of heavy cloth. Gentleness is of great importance in operating. One should not pull and tug.

DR F H FALLS, Chicago. Dr Greenhill didn't stress sufficiently the fact that one may have considerable vomiting and straining during local anesthesia and many times one has to give up and resort to general anesthesia because of it. As to the question whether local anesthesia ought to be used in a case in which one can just as well use general anesthesia, I would prefer ether anesthesia. It takes longer to do the same operation under local anesthesia and in spite of music and the various methods of distracting the patient's attention, first stressed in this country by Dr Farr of Minneapolis, many patients do remember certain facts about the operation. They have a certain amount of pain and nervous apprehension, and if one can as well use general anesthesia I believe one should. Unquestionably, local anesthesia increases the operative time. In gynecologic practice, particularly in older women, I think it ought to be stressed that local anesthesia has its greatest value. I have removed an intraligamentous ovarian cyst as large as a basketball in a woman 65 years of age and she did not know that she had been in the operating room. I always precede local anesthesia by the use of morphine, $\frac{1}{4}$ grain (16 mg), and scopolamine, $\frac{1}{150}$ grain (0.4 mg), one hour before operation and repeat the scopolamine one-half hour later. The patients come to the operating room so depressed by the morphine and scopolamine that, if local infiltration is added, they frequently have no memory of the operation or of any immediate postoperative discomfort. It is important to remember that one cannot get as good results in a strange hospital, using local anesthesia. I found that operating at the County Hospital it is much more difficult to get the result than it is to get it at my own clinic in the Research and Educational Hospital at Illinois. A trained personnel is required to assist in doing this type of work. Every detail must be carefully followed out and time, patience and gentleness are required of all participants. One must be careful to examine patients that one is going to operate on under local anesthesia for a possible underlying thyrotoxicosis. I had two patients who developed thyroid shock following local anesthesia, in whom the latent goiter symptoms were not noticed preoperatively.

DR J P GREENHILL, Chicago. Dr DeLee mentioned Webster as a pioneer in the use of local anesthesia. Another pioneer to whom a great deal of credit is due for repeatedly showing the great value of local anesthesia is George Gellhorn of St. Louis. Dr DeLee reported some bad results with the accidental use of 5 per cent procaine hydrochloride. Most operators who use procaine employ a 0.5 per cent solution but

almost the identical results may be obtained with a one third or even 0.25 per cent solution. I agree that it is advisable in most cases, but by no means all, to talk to the patient during the operation. A little encouragement now and then is necessary for some patients. A few individuals become drowsy and fall asleep before the operation is ended. Preceding gynecologic operations, the patients are given morphine not later than forty-five minutes before the operation and most of the patients come into the operating room very drowsy. As explained in the paper, chief reliance is placed on morphine for the obstetric patients also. Older women are particularly good subjects, as Dr Falls brought out. Operations, particularly vaginal ones, may be performed on elderly women without any difficulty at all and most of the patients sleep practically all the time during the operation. I take exception to what Dr Falls said about the necessity for a trained personnel. I agree that in many hospitals there is difficulty getting proper paraphernalia for local anesthesia, but in reality all that is needed is two or three good syringes and a few long needles in addition to the local anesthetic. The operator himself does all the injecting but he must warn the assistants to be gentle and deliberate in all their manipulations.

LOCAL INFILTRATION ANESTHESIA OF THE PROSTATE PRELIMINARY TO RESECTION

WILLIAM N WISHARD, JR, MD

H G HAMER, MD

AND

H O MERTZ, MD

INDIANAPOLIS

In the early fall of 1932 we had under our care an elderly patient with a fibrotic contracture of the vesical orifice occurring several years after prostatectomy. Cystoscopic examination revealed no prostatic recurrence but a relatively small amount of scar tissue producing a considerable degree of obstruction. The patient also had marked coronary disease, which, a medical consultant felt, constituted an anesthetic risk out of all proportion to the proposed operative risk of transurethral resection. Using only a topical application of cocaine, we quickly resected four or five small pieces of tissue from the floor of the vesical orifice with the McCarthy electrotome. Save for moderate pain during the time the cutting current was actually in use, the patient did not experience any great discomfort, making an uneventful recovery with satisfactory functional results. In retrospect, it occurred to us that, if the tissue to be resected could be infiltrated with procaine as is done with the needle in the Caulk punch, the operation could be carried out painlessly with no other risk than that entailed by the resection itself.

We therefore made an instrument for this purpose by securing the distal portion of a 21 gage hypodermic needle in the end of a No. 6 ureteral catheter. Using this in a catheterizing cystoscope, we infiltrated the tissue about the vesical orifice with procaine hydrochloride in our next case of contracture and elevation of the vesical orifice. The tissue was resected without pain. Shortly after, we found an earlier report by Frischer describing a similar needle attached to a flexible metal tube which could be used through a cystoscope. Still earlier, in 1926, Hyams devised a method to be used endovesically preliminary to diathermy.

From the Department of Genito-Urinary Surgery, Indiana University School of Medicine.
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

It then occurred to one of us (W) that a needle on a straight tube might be substituted for the cutting loop in the electrotome, thus eliminating the use of two separate instruments. Such a needle was made for us by a jeweler. It gave satisfactory results until we attempted to use it on a moderately well developed lateral and median lobe hypertrophy of the prostate. After the first few cuts were made we found that infiltration had not been extensive enough. We then found a description of Ryall's needle for use in his resectoscope in which the needle and lens system travel together during the excursion of the rack and pinion device.

Knowing that suprapubic prostatectomy had been successfully done under local infiltration from above, we felt that transurethral resection under local infiltration anesthesia would be successful if the gland could be injected deeply enough. The fact that the needles we were using operated almost parallel to the long axis of the urethra seemed to offer the explanation as to why the deeper portions did not become anesthetized. If a needle could be introduced into the prostatic urethra and then turned at a right angle to the sheath of the instrument, it could be plunged far enough into the prostate to give anesthesia of proper depth.

An instrument of this principle, designed by one of us (W), was therefore made and has been used by us. While the needle did not actually operate at a right angle to the resectoscope sheath, it deflected at a sufficiently acute angle so that it would enter at least 1.5 cm into the prostatic tissue. The details are shown in figures 1 and 2. The outer sheath has the same diameter as the cutting loop and is a little shorter. The back end of this tube is secured by a small key, which slides over the front of the rack of the resectoscope. The inner end comes almost but not quite to the floor

Fig 1—Parts of infiltrator. A, outer deflecting tube; B, inner needle-bearing tube; C, needle; D, tape that fastens needle to tube; E, key that secures outer tube to rack of electrotome; F, syringe connection.

of the fenestrum of the resectoscope sheath. This inner end tapers off to a deflecting tube of 18 gage. Into this outer deflecting tube, the needle-bearing tube is inserted before the instrument is fastened in the resectoscope. The needle itself, a 25 gage detachable dental needle of rustless steel, screws on to the end of the inner tube, which is then inserted into the outer sheath. The assembled device is placed into the slot in the resectoscope customarily occupied by the cutting

loop. The outer deflecting sheath is secured behind by a key fastened over the rack, while the inner needle-bearing tube slips in behind to the set-screw which usually clasps the electrode. A small tap connected to a short urethral catheter screws in the side of this needle-bearing tube just in front of the set-screw. The other end of the catheter is attached to a 10 cc luer syringe. The entire assembled mechanism is then placed in the bakelite sheath of the McCarthy electrotome after the latter has been introduced in the urethra. Thus, when the pinion is pulled clear back, the needle

Fig 2—Infiltrator fully assembled ready to insert in electrotome.

is entirely concealed within the deflecting outer tube so that the resectoscope can be moved to and fro at will. When the desired field is seen in the lens system, the pinion is moved forward. This introduces the needle under direct vision into the prostatic tissue at a sufficiently acute angle so that it penetrates the gland quite deeply, as shown in the roentgenogram of a post-mortem specimen (fig 3).

Our procedure is as follows. The customary pre-operative narcotic is given. Half an hour before operation, 15 cc of 2 per cent metyline solution is introduced by catheter into the bladder following thorough vesical irrigation. If previous cystoscopic examination has demonstrated good bladder tolerance to distention, this may be omitted. When the patient is draped, the urethra is irrigated and anesthetized with three 15 mg cocaine hydrochloride tablets introduced through the Lewis dry applicator. The resectoscope is then placed in the urethra armed with the needle instead of the cutting electrode. Starting on the floor of the prostatic urethra at the margin of the vesical orifice, the needle is introduced into the prostate. After suction has been made with the syringe, to make sure that the needle is not in a blood vessel, 2 per cent solution of procaine hydrochloride (with 0.3 cc of 1:1,000 solution of epinephrine to 30 cc of procaine) is injected. From 1 to 4 cc is usually injected at each introduction of the needle. The needle is withdrawn and reintroduced a little distally. The floor of the prostatic urethra is thus infiltrated outward as far as the verumontanum. The lateral lobes are then infiltrated. Some bulging and blanching of the tissues are noticed if the needle is superficially placed beneath the mucosa. If deeply embedded, such is not the case. It never seriously interferes with vision or subsequent cutting. We have used as little as 6 cc for the complete anesthesia, and as much as 85 cc. The exact amount required depends on the quantity of tissue to be resected. From 20 to 30 cc is a fair average. Five or ten minutes is the usual time required. Just as success grows by continued experience with resection, so does the efficacy of anesthesia increase by its continued use.

We have not noted any immediate untoward systemic action from the procedure, nor have we as yet been aware of an intravenous injection. There is usually a slight transient acceleration of the pulse. The infiltration causes little or no pain. We have not observed any increased tendency to postoperative hemorrhage by the use of epinephrine in the solution, though it may give a clearer operative field. We must mention, however, that the only resection we have ever performed which required subsequent cystostomy to control postoperative hemorrhage was done under local infiltration. This occurred six hours after operation, the urine being only faintly pink until a sudden massive hemorrhage developed.

INDICATIONS

Local infiltration produces adequate anesthesia for resection of contracture and elevation of the vesical orifice, median bar and middle and lateral lobe hyper-

Fig. 3—Roentgenographic appearance of lateral lobes of prostate infiltrated with sodium iodide. Diffuse penetration of solution through out entire lobe may be noted.

trophy. While we have employed it on large adenomatous hypertrophies, we do not advocate its use in such cases as a routine. We believe that local infiltration anesthesia is particularly useful on patients with some systemic contraindication to inhalation or spinal anesthesia. The immediate risk of these anesthetics to the patient with marked arteriosclerotic heart disease is at times equal to or greater than the operative risk itself. On the other hand, we have not found that local infiltration has any effect on the incidence of postoperative complications (other than those directly connected with inhalation or spinal anesthesia).

CONTRAINDICATIONS

Extreme vesical intolerance to distention, demonstrated by preliminary cystoscopic examination, constitutes a serious objection to local anesthesia, as does intolerance to urethral instrumentation. While the prostate itself may be satisfactorily anesthetized, the bladder and urethra cannot be so well handled. Very

large, adenomatous prostates, the resection of which requires a long time, are not particularly suitable for local infiltration. A series of twenty consecutive resections was completed before we finally had to resort to transsacral anesthesia because preliminary cystoscopic examination and overdistention were so painful. Extremely nervous, excitable or uncooperative patients should not be subjected to resection under local anesthesia. Concurrent diabetes may also be a valid contraindication, though our experience with this is limited to one patient, whose convalescence was uneventful.

COMMENT

Infiltration anesthesia on any part of the body may be unsuccessful, this applies likewise to a certain percentage of prostatic cases. There are, however, other objections which might be raised. Foremost is the possibility of disseminating infected fluid throughout the gland. The needle may be sterile, but its point passes through a potentially infected medium before entering the gland. Indeed, we have found methylene blue, injected experimentally in autopsy specimens clear out to the periphery of the prostate, though the needle penetrated only 1.5 cm. While our experience is not large, we have found that in actual practice this objection is largely academic. Regardless of the type of anesthesia, a denuded surface follows resection, yet serious infection is the exception rather than the rule. Convalescence is no different following infiltration than after other anesthetics. It is possible, however, that future experience may alter our views.

One might also object that infiltration would produce enough local edema to impair vision or retard cutting. We have had no difficulty with vision. What theoretical problems are presented to the electric current, such as increased resistance, we do not know, but we have not observed any diminution in the electrode's ability to remove loops of tissue when the cutting current is applied. Bleeding is often though by no means always, somewhat diminished. Coagulation of vessels is not hindered.

Accidental intravenous injection of procaine may be avoided by routine aspiration after the needle is introduced and before injection is made.

If flexible rustless steel 25 gage needles are used, we do not believe that bending of the needle itself constitutes serious danger of breaking. In an autopsy specimen we inserted the needle as far as possible into a lateral prostatic lobe, exactly as one would do in practice, and then deliberately moved the entire resectoscope to and fro in the urethra with the rack and pinion held tightly, exactly as one would not do in practice. The specimen was then opened. The urethra was, of course, badly lacerated. The needle was twisted and bent but not broken. This test was far more extreme than any demands placed on the needle in actual practice. The needle itself, being detachable from its carrier tube, may be changed at each operation if one so desires. We used one needle in fifteen cases, changing it thereafter as a matter of precaution.

RESULTS

We have done thirty-three resections under local infiltration anesthesia. One lasted ninety minutes with good anesthesia to the end, though this is an unusually long duration. The majority experienced only slight discomfort. In only one case did gas have to be administered because of insufficient anesthesia.

The amount of tissue removed at each resection varied from 1 to 20 Gm.

COMPLICATIONS

In this series of resections we have had three serious complications with recovery and two deaths. One patient developed femoral phlebitis two weeks after operation. Another had a postoperative hemorrhage as previously mentioned while a third had facial erysipelas with recovery. Erysipelas caused the death of one patient. An epidemic of erysipelas was present at the time and we do not believe that it can be directly charged to the type of operation. The second death was due to hemiplegia twenty-four hours after operation on a man of 85. He had marked arteriosclerosis without hypertension and was uræmic on admission to the hospital. His renal function improved with preliminary catheter drainage so that we thought the risk justifiable. While death was unquestionably an after-math of resection we are inclined to believe that the choice of anesthesia was not a factor.

SUMMARY

An instrument is presented to produce infiltration anesthesia of the prostate preliminary to transurethral resection. Its essential feature is that the needle deflects at an acute angle, permitting deeper anesthesia than we have obtained when using needles operating parallel to the long axis of the resectoscope and urethra. Its chief field of usefulness lies in obviating the immediate danger of inhalation, spinal or sacral anesthetics in certain bad risk patients.

1711 North Capitol Avenue

ABSTRACT OF DISCUSSION

DR G. J. THOMPSON, Rochester, Minn. The advantages of local anesthesia over spinal or general anesthesia are obvious. Many of the headaches and gastric upsets that occur during and after operation under spinal anesthesia can be avoided by resorting to local anesthesia. During the last two years Dr Bumpus and I have performed 450 operations and have usually employed spinal anesthesia. In spinal anesthesia for transurethral prostatic resection only a small amount of procaine need be used in most instances, for aged patients metabolize procaine slowly. Recently we used 50 mg of procaine hydrochloride in 2 cc of spinal fluid and resected 26 Gm of tissue in a period of forty-five minutes, the anesthesia lasting very satisfactorily. The disadvantages in this method are the time consumed, the distortion of landmarks by the infiltration, and lack of relaxation of the vesical neck. I am sure the relaxation produced by spinal anesthesia is of great value for it permits the introduction of the instrument with a small amount of trauma, a factor of great importance in minimizing postoperative fever and toxemia. The necessity of supplementing this method with other forms of anesthesia is the only other disadvantage of which I can think.

DR H. M. STANG, Eau Claire, Wis. The idea of local infiltration of prostatic bars or small papillomas at the vesical neck is not new but the method of doing it was cumbersome and the procedure was not very successful. The authors present an instrument that will prove satisfactory in the hands of men who are doing prostatic resection and no doubt it will be of benefit in selected cases. Many operators will undoubtedly use the method that they have found successful, the spinal, trans-sacral or gas-oxygen anesthesia. I do not see any contraindications to this method except the manipulations necessary and the time consumed in the added manipulation in the urethra.

DR JULIUS FRISCHER, Kansas City, Mo. I wish to show that the old needle has been improved on. At first, my chief inducement to the use of prostatic anesthesia was that I would operate under local infiltration. With the advancement of transurethral work regional anesthesia such as caudal, sacral and spinal was added. Even now many patients object to these types of anesthesia but will submit to prostatic resection if I am willing to use local anesthesia. Ninety per cent of my cases have been

successfully handled with local infiltration anesthesia. It has been only during the past year that I have employed some regional methods of anesthesia. Preliminary to operative procedure when bladders are infected I have always been careful to have as clean a field as possible. The patients are prepared in the following manner: They are given sodium amytal, 3 grains (0.2 Gm.) on retiring the night before the operation, another 3 grains in the morning and one-fourth grain (0.016 Gm.) of morphine one hour before the operation. Four separate injections are made through the urethra into the bladder, 1 ounce (30 cc.) of a 2 per cent solution of procaine hydrochloride in physiologic solution of sodium chloride being used. These injections are made at fifteen minute intervals just prior to the operative procedure. For infiltration I make four separate injections of 5 cc each of a 1 per cent solution of procaine hydrochloride in physiologic solution of sodium chloride directly in the field in which I am resecting or coagulating. Local anesthesia is accomplished by means of a long flexible needle used through the operating cystoscope, the operating urethrocystoscope or the proctoscope. This needle is made of a flexible silver tubing, covered with a spiral sheath which makes it sufficiently resilient to penetrate fibrous tissues. The needle proper is 1.125 cm long, 20 gage and the shaft is 9 F caliber. The entire needle measures 15 inches in length. This added length facilitates local and infiltration anesthesia for other conditions about the ureteral orifices and in the bladder proper. I have found this needle practical because it can be sterilized by boiling because it accommodates the Luer lock syringe, and because it is flexible yet resilient and is very durable.

DR GEORGE H. EWELE, Madison, Wis. At the Detroit meeting I presented a method for transurethral anesthesia and am sorry that many of my friends misunderstood me. I was trying to differentiate between spinal and sacral anesthesia. What I was doing was introducing into the dural sac from 50 to 75 mg of procaine hydrochloride, and the procedure is carried out with the patient in the sitting posture. It can be done in any space one wishes, for the solution is very heavy and will not run to the tip of the dural sac. If the patient is allowed to remain in the sitting position for ten minutes one can put him in any position one wishes and the fluid will not travel. I have never yet experienced any change in blood pressure, because the anesthesia does not go above the sacral nerve.

DR J. A. HAYES, New York. There is no doubt that anesthesia by direct injection is a valuable aid in the treatment of urethral and urethrovaginal pathologic conditions. At the annual meeting of the American Urological Association in Boston in 1926, Dr McCarthy presented an instrument called the hypodermic electrode devised by me for making such direct injections. The instrument is of two types, one flexible the other rigid, each threaded for a tiny detachable needle, which can be used for the injection of an anesthetic or the application of diathermy. On the distal portion there are two terminals, one for attachment of a Luer syringe, the other for connection with the cord from a diathermy apparatus. The flexible type is made by Bard & Company, the rigid by the American Cystoscope Makers. They differ very little in principle from the instrument shown by Dr Frischer. I use the instrument for anesthetizing and the endo-urethral removal of inflammatory tissue excrescences, polypoid cystic elevations and small projecting portions of prostatic tissue remaining after prostatectomy. The use of infiltration anesthesia preliminary to the removal of such cicatricial obstructions as fibrous elevations at the posterior vesical lip and coarctations of the vesical sphincter has advantages. For resection of the larger types of hypertrophy of the prostate unless warranted by existing conditions, the added traumatism, possible dissemination of infection, and increased danger of secondary bleeding can hardly compensate for the slight difference in risk between this and caudal or transsacral anesthesia.

DR W. N. WISHARD, JR, Indianapolis. The question of the time element has been brought up. This has never been very great, ten minutes being the usual period. We do not wish to cast any reflections on spinal or caudal anesthesia. We have used both and have had no trouble, but we have always had some apprehension until the patient was back in bed. We have used epinephrine in several cases, it seemed to help in preventing the immediate hemorrhage and did not cause delayed bleeding.

GRANULOMA COCCIDIOIDES

FURTHER OBSERVATIONS ON THE USE OF ANTIMONY AND POTASSIUM TARTRATE AND THE ROENTGEN RAYS IN TREATMENT, REPORT OF AN ADDITIONAL CASE

C C TOMLINSON, M D

AND

PAUL BANCROFT M S

OMAHA

It is our purpose to present evidence supporting that brought forth previously, first by Guy and Jacob¹ and later by ourselves, indicating that antimony and potassium tartrate, given intravenously, combined with roentgen therapy, applied locally, is of value in the treatment of granuloma coccidioides.

In 1927 Guy and Jacob reported the first apparent cure of coccidioidal granuloma by means of these measures. Their patient had shown little or no improvement under various other forms of treatment including iodides and the roentgen rays. Four months treatment on alternate days, using a 1 per cent solution of antimony and potassium tartrate in doses up to 7 cc apparently resulted in complete healing. Roentgen therapy was used during these four months in one-half unit doses at ten day intervals.

A month after treatment was discontinued the disease recurred but subsided fairly promptly "with a few tartar emetic and roentgen treatments." These authors found that the roentgen treatment alone did not bring about material improvement. They also noted that one of the patient's lesions which was not treated with the roentgen rays while antimony and potassium tartrate was being given did not heal as rapidly as the others. In other words, it seemed to them that the two procedures were complementary.

In 1928, having followed this plan of treatment, we reported "definite improvement and possible cure" in a case of granuloma coccidioides in a patient who had contracted the disease while working with the fungus coccidioides in the laboratory.

A brief review of our previous report and the progress in this case to date follow.

REPORT OF CASES

CASE 1—P B, a man, aged 26, a fellow in the department of bacteriology at the University of Nebraska, after a prolonged period of research with *Coccidioides immitis*, became ill with moderate chills and fever, general malaise and a hacky cough which on one occasion was productive of blood-streaked sputum. Within two weeks of the onset of these symptoms an abscess developed on the plantar surface of the left foot. This was incised and drained. The fungus coccidioides was recovered in the fresh preparation of pus by culture and through inoculation into a guinea-pig. Three months' treatment on alternate days with doses of from 2 to 8 cc. of a 1 per cent solution of antimony and potassium tartrate given intravenously and one-half skin unit of unfiltered roentgen rays at intervals of from ten to fourteen days produced complete healing.

No further difficulty was experienced until May, 1931, almost four years after the original trouble, when the patient again became ill with chills and fever. One week after the onset of these symptoms a filbert-sized nodule appeared about the mid-outer surface of the left leg from which pus containing the

fungus coccidioides was aspirated. We immediately returned to the use of antimony and potassium tartrate and roentgen treatment in the manner previously described, and healing was complete in four weeks.

The patient has appeared to be in excellent health during the past two years, but we have continued to give him biweekly injections of the solution of antimony and potassium tartrate in doses of 5 cc.

Comment—In view of this patient's prolonged laboratory contact with the organism and the prodromal illness marked by cough and bloody sputum, we believe it can be reasonably assumed that this case began as a pulmonary coccidioidal infection, the result of inhaling spores of the fungus in the laboratory.

It is to be noted that although the original attack was of several weeks' duration when the diagnosis was established, this treatment resulted in complete healing of the foot and apparent normal health over a period of four years. Early recognition and treatment of the recurrent attack resulted in complete healing within four weeks and the patient has been in excellent health

Fig 1 (case 2)—Ulcers on the knees before treatment

during the past two years. This succession of events points to the efficacy of this treatment, and we think also suggests a probable need for carrying treatment quite indefinitely beyond the stage of complete healing of the lesions.

CASE 2—F P, a white American-born boy of 7, was brought to one of us (C C T) on June 25, 1929, because of ulcers on the knees. The family history and past history were essentially unimportant.

One year before the patient was brought to us he had abraded his knees on a concrete driveway. Within a few days after this accident he was taken on a two weeks automobile journey through Texas and Louisiana. From the time he left Omaha until he returned, superficial ulcerations developed at the site of the abrasions on the knees, which during the succeeding weeks became larger and deeper and drained a great deal of pus. He was placed in a local hospital where he remained almost continuously from early October, 1928, until late June, 1929, during which time various types of treatment, including roentgen therapy, wet dressings, ointments, cautery and excision failed to influence the progress of the ulcers.

When seen by us on June 25, 1929, he was markedly anemic and undernourished. His oral temperature was 100 F. Our examination revealed four ulcers about the left knee and five

2. Tomlinson C C and Bancroft Paul Granuloma Coccidioides J A M A 91 947 (Sept 29) 1928

about the right knee, varying from 2 to 10 cm in diameter, with several smaller satellite ulcers between and about the larger ones. These ulcers, roughly oval in outline, were of a distinctly crateriform type, each having a granulomatous base and being covered by a firmly adherent thick purulent crust. There were marked contractures of both knees (fig 1).

Search for coccidioidal organisms in the pus (fresh alkali preparation) was negative. Cultures on Sabouraud's medium showed a moist growth on the fourth day. Animals were inoculated with fresh pus from the ulcers and from the culture material. In these animals lesions developed in which the spheroidal double contoured refractile bodies characteristic of *Coccidioides immitis* were found (fig 2).

Treatment, in addition to general supportive measures consisted of wet dressings with a weak solution of corrosive mercuric chloride, roentgen therapy and intravenous injections of antimony and potassium tartrate. Each lesion was treated with from one-fourth to one half skin unit dose of unfiltered roentgen rays at intervals of from seven to thirty days, a total of ten such treatments being given. Sixty-two intravenous injections of antimony and potassium tartrate were given over a period of one hundred and eighty-four days, the usual interval being three days, and the longest interval twenty eight days. A 1 per cent solution of antimony and potassium tartrate was employed in doses of 5 cc. No untoward reaction was noted.

From the beginning there was slow but definite improvement. The ulcers became clean and healthy looking within six weeks from the beginning of treatment but owing to their size some of the larger ulcers required eight months for complete healing. There has been no recurrence, and the patient is now a strong, active boy showing only scars of the healed ulcers (fig 3) as evidence of his previous trouble. He has had no treatment of any kind since Dec 25, 1929.

Comment—We are not at all certain as to the portal of entry in this case or as to the time the infection was acquired. In regard to this case, however we are quite certain of two things. First, that no treatment that the patient received over the fifteen months period prior to the time we saw him had any curative value. Second, that after he was started on intravenous injections of antimony and potassium tartrate and roentgen therapy

received many types of treatment including antimony and potassium tartrate and roentgen therapy, and although Zeisler's report would seem to indicate rather definite improvement following the use of antimony and potassium tartrate and roentgen therapy, it is our opinion that had these measures been used to the exclusion of others over a longer period of time better results might have been obtained. During the twelve days he was in our care he received one half skin unit

Fig. 3 (case 2)—Scars of healed lesions three years after treatment was completed

of roentgen rays and eight doses of 5 cc each of a 1 per cent solution of antimony and potassium tartrate, which in this short time brought about definite improvement of all the lesions.

Comment—We believe that this case is of little value in our report and include it only for the sake of completeness.

CONCLUSIONS

We believe that our first two case reports are evidence that prolonged treatment with intravenous injections of antimony and potassium tartrate and local roentgen therapy is effective in the treatment of granuloma coccidioides. Admitting that our two apparent cures and that of Guy and Jacob do not supply conclusive evidence, we know of no other report in which comparable results have been sustained over a period of several years. We are convinced that the treatment must be continued for a long time.

ABSTRACT OF DISCUSSION

DR GEORGE M LEWIS, New York. Granuloma coccidioides has probably shown the highest mortality and has proved the most resistant to therapy of all the rarer mycoses. The iodides, which are of great service in many fungous diseases, are of little value here. Although the report does not contain a large series of cases, this does not detract from the observations, since the authors are dealing with a notoriously persistent and progressive disease with no likelihood of spontaneous cure. Nor does the well established curative effect of other remedies, such as colloidal copper and coccidioidin mean that an ideal treatment is known. From the reports of Jacobson and many others it is evident that roentgen therapy, colloidal copper and coccidioidin do not cure every case of granuloma coccidioides. It is thus possible that some patients will do well on this regimen and other patients will respond more favorably to the combined use of x-rays and antimony and potassium tartrate. A remarkable feature in the first case history was the interval of four years between the complete subjective and objective disappearance of the disease and the subsequent development of new lesions. The question arises whether the infection remained dormant during this interval, as in syphilis, or the patient became reinfected. Because of the first possibility the

Fig 2 (case 2)—*Coccidioides immitis* section from a guinea pig inoculated with material from the patient's ulcers

he improved steadily until healed, and has had no manifestation of the disease since treatment was completed three and a half years ago.

CASE 3 (This case was previously reported by Zeisler³)—E J S, a man aged 38, was seen twelve days prior to his death by suicide. During the last year of his life the patient

³ Zeisler E P. Chronic Coccidioidal Dermatitis. Arch Derm & Syph 23: 52 (Jan) 1932.

authors do well to emphasize the importance of continuing treatment long after all evidence of the disease has disappeared. This is in line with the recognized management of other deep fungous infections, such as actinomycosis and sporotrichosis, in which relapses may occur if therapy is discontinued coincidentally with the disappearance of the skin manifestations.

Dr. EDWIN P. ZEISLER, Chicago. I should like to comment briefly on the patient the authors mentioned who had been under my care at the Cook County Hospital. The lesions in this case were entirely dermal and were unusually extensive. No pulmonary, osseous or subcutaneous involvement could be demonstrated. Before the patient came to me, many different methods of treatment had been used, including the arsenophenamines and iodides. During a period of three months I administered antimony and potassium tartrate alternating with colloidal copper, with complete retrogression of the lesions and I thought that the patient was cured. He remained well for three months, but at the end of that time new lesions developed which did not respond to further treatment. Regarding the efficiency of the drugs used, I had difficulty in arriving at any conclusion, but it seemed that colloidal copper was better than antimony and potassium tartrate. One preparation of colloidal copper sulphide made in Chicago was tried and proved to be entirely ineffective. A French preparation was found to be the most effective but unfortunately was very expensive. The one thing I have learned about the treatment of coccidioidal granuloma is that the treatment must be prolonged even after apparent cure takes place and I believe that the combination of roentgenotherapy with these two drugs will give the best results. Another point is that the few cases reported as cured were purely dermal. I think that no case presenting pulmonary lesions has been cured, a few cases of osseous involvement have been cured by amputation.

Dr. HOWARD MORROW, San Francisco. I concur in Dr. Zeisler's remarks that these cases are not cured even when we consider them cured. In California we see a great many cases of granuloma coccidioides and have come to consider the prognosis very serious. It has been our experience that 60 per cent of the patients die within a few years. When a patient is fortunate enough to have lesions on a limb only amputation may cure the disease, but such cases are rare. I have tried antimony, vaccines made from the fungus, copper typhoid vaccines and protherapy but am of the opinion that nothing will cure granuloma coccidioides. Occasionally I see a patient in whom a certain resistance has been built up against the infection and I have wondered whether the fungus was of a low-grade virulence, but I have come to the conclusion that it is not a case of virulence of the organism but of resistance on the part of the patient. Some years ago I had a seafaring man who had coccidioides of the knee. He had his thigh amputated and apparently remained well for fifteen years. He also had a mild papular and pustular dermatitis of the brow and upper eyelid, cultures of which yielded the Coccidioides organism. I could not understand why this eruption did not clear up under therapy or why the disease did not progress. I thought that the virulence of the organism was low, but on animal inoculation this was proved to be just as virulent as the most rabid type of Coccidioides. Therefore, I came to the conclusion that it was a natural resistance. The patient still has the mild papulo-pustular eruption of the brow and upper eyelid. Cultures still show the fungus, and he still seems to be in perfect health. Perhaps the primary lesion on the knee enabled him to build up a resistance.

Dr. FRED D. WEIDMAN, Philadelphia. Reports of this kind open the question whether it is the resistance of the host against the organism that is responsible for cure, or whether species of different (attenuated) virulence are concerned. Turning to granuloma coccidioides in particular the South Americans have written much that bears on today's paper. Recently Almeida has pointed out that there are different organisms concerned in what has been reported as coccidioidal granuloma in Brazil. Dr. Jordon of my laboratory has imported these organisms from South America and compared them with North American strains. I now can confirm the contention of Almeida. In South America there are two or perhaps three forms. The first is identical with what is found in North America. The second is an entirely different organism and the disease is also

different clinically. It produces very scanty lesions in animals, the disease runs a mild course and is amenable to treatment with antimony and potassium tartrate, hence the reports from South America of successful results with this treatment must be taken with reservations, for what they are treating there is for the most part an entirely different disease. However, I can vouch that this organism, *Paracoccidioides brasiliensis*, was not concerned in Tomlinson and Bancroft's case. I had the good fortune to be mixed up with the original case of cure of coccidioidal granuloma reported by Guy and Jacob. That patient had coccidioidal arthritis four years ago. Recently Dr. Guy told me that the man is now in apparently good health. I recall that the organism was comparatively nonvirulent for laboratory animals. Contrary to the usual results the lesions consisted simply of a multiple serositis. Probably there are other differences in virulence but this is the only case I have known in which a definite difference was demonstrated, and this was a genuine case of *Coccidioides immitis* infection—not the Brazilian disease. I feel sure that one may get organisms of lower virulence within a fungus species but as Dr. Morrow stated cure cannot be expected consistently in coccidioidal granuloma.

Dr. CHARLES C. TOMLINSON, Omaha. Answering the question as to whether the second attack in case I was a new infection or the lighting up of a dormant infection we feel quite sure that it was the latter as this is quite the usual history in this disease. Dr. Morrow favors amputation when the disease is confined to an extremity but in our case I reasoned that the primary focus was pulmonary and that amputation would not necessarily protect against development of the infection in other locations. I cannot quite understand why Dr. Zeisler favors colloidal copper, as his report states that his case cleared up and remained clear for a period of three or four months following treatment with antimony and potassium tartrate. Having seen two cases become symptom free and remain so under this plan of treatment we feel convinced of its efficacy and want to encourage its use particularly by the men from California, who see this disease most frequently.

BILATERAL CORONARY OCCLUSION WITH MITRAL STENOSIS

WITH A CONSIDERATION OF THE COMPENSATORY
CIRCULATORY FACTORS IN THE HEART

SOLOMON R. SLATER, M.D.

Associate Attending Physician, Division of Cardiology, Assistant in
Pathology, Jewish Hospital of Brooklyn

AND

DANIEL KORNBLUM, M.D.

Clinical Assistant, Department of Cardiology, Jewish Hospital
of Brooklyn
BROOKLYN

An example of both mitral stenosis and bilateral coronary occlusion has not been found in the literature. The case reported here, presenting a tight mitral stenosis and an occlusion of all the main coronary arteries, furnishes an interesting example of the remarkable potentialities of the various compensatory mechanisms of the heart and its blood supply.

REPORT OF CASE

S. B., a white man aged 63 a tailor was admitted to the Brooklyn Jewish Hospital in the general medical service of Dr. Joseph Rosenthal, complaining of generalized weakness, dyspnea on exertion and edema of the ankles.

Three years before, he had an attack of pain over the precordium and shortness of breath. He was taken to a hospital where he stayed three weeks. Since then he had remained quite well and was able to go to work daily. Slight dyspnea on exertion was the only symptom that persisted. About three weeks before admission he first noted increasing generalized weakness, with increasing dyspnea which forced him to stop working one week later. At this time he first noted swelling

of the ankles which became progressively more marked. There was no precordial pain nor palpitation of the heart. Questioning regarding symptoms referable to the various tracts revealed nothing of note. There was no history of a venereal infection.

The patient was poorly developed and appeared moderately ill. He had a pale, muddy complexion. Slight cyanosis and dyspnea were present. The temperature was normal, pulse 80, respiration 20, blood pressure 110 systolic, 74 diastolic. The patient was found to be a hyposensitive type by Libman's test. A moderate sclerosis of the vessels of the overgrounds was present. The heart was found to be of normal size by percussion. The apex impulse was diffuse in the region of the midclavicular line in the left fifth interspace. The heart sounds were rather distant. A moderate extrasystolic irregularity was present. There was a prolonged mid diastolic murmur at the apex. Dulness was present over the left base, and flatness over the right base of the lungs. At the former area, moist crepitant rales were present while breath sounds were entirely absent at the latter area. The liver edge was palpable from two to three fingerbreadths below the costal margin. No fluid in the abdomen was perceived. A moderate pitting, edema of both legs and arms was present.

A gallop rhythm was present associated with a murmur during the gallop, which suggested a diagnosis of mitral stenosis with a prolonged PR interval. Electrocardiographic tracings the next day revealed a partial auriculoventricular block consisting of a PR interval of 0.26 second and occasional dropped beats. The complexes were all of low voltage the highest QRS being 5 mm. A definite right axis deviation was present. The T waves were diphasic in leads I and II and inverted in lead III. A teleroentgenogram of the heart showed a slight increase in the transverse diameter and a flattening of the left border suggestive of mitral stenosis. There was an increase in the lung markings in both bases and evidence of a small amount of fluid in the costophrenic sinus. Wassermann and Kahn tests were negative. There was slight fever up to 101.8 F from the fourth to the eleventh day of his stay in the hospital.

Saltargan, 1 cc, was injected intramuscularly shortly after admission and repeated every five days. Ammonium chloride, 20 grams (13 Gm) three times a day and digitalis, 2 grams (0.13 Gm) twice a day were administered. A favorable water balance was soon obtained and improvement thereafter was marked. By the end of the second week of his stay in the hospital, the edema had disappeared, the liver had receded so that it was barely palpable under the costal margin and the signs in the chest had cleared. For the last five days in the hospital the patient was up and about with no symptoms whatever. He was discharged from the hospital three weeks after admission feeling perfectly well and having no signs of decompensation. The diagnosis on discharge was rheumatic fever (inactive), generalized arteriosclerosis, mitral stenosis and insufficiency, coronary sclerosis, fibrosis of the myocardium, and congestive failure improved.

The patient walked out of the hospital in high spirits but on entering a taxicab he suddenly fell. On examination immediately afterward, he was pronounced dead.

At autopsy the lesions found besides those of the heart were infarctions in the lung, chronic cholecystitis, fatty degeneration of the liver, cyst in the pituitary gland, and cerebral edema and congestion.

The heart weighed 330 Gm. It was spherical and measured 8 cm from the base to the apex of the ventricles. The visceral epicardium showed patches of thickening but no adhesions and no fresh pericarditis were found. Both atria and the right ventricle were somewhat dilated and hypertrophied. The foramen ovale was closed. Some fresh adherent thrombi were present in the right auricular appendage and at the apex of the right ventricle. The myocardium besides that of the left ventricle was everywhere of normal appearance, no areas of softening, necrosis, fatty changes nor fibrous streaks being present. Microscopic examination revealed however a slight increase of the interstitial tissue, small patches of fibrosis, localized areas of sparse lymphocytic infiltration, and a slight granular degeneration of the muscle cells.

The changes in the left ventricular wall for the most part were grossly of fibrous nature. The fibrosis appeared localized

mainly in two areas, one of these was at the apex anteriorly, where the ventricular wall was thinned to 5 mm and the muscle was almost completely replaced by silvery firm fibrous tissue. The other area was at the base adjacent to the septum posteriorly. There was some fibrosis connecting these areas along the posterior wall of the ventricle near the septum. The remaining musculature showed no fibrosis but was dark red, and small streaks of purplish red were present occasionally throughout except for the basal portions, which appeared entirely uninvolved. There were no areas of softening or necrosis. The fibrotic changes extended to the septum, so that its posterior third and its entire apical portion were involved. The remaining part of the septum showed no changes. Microscopically all the sections of the left ventricular myocardium presented varying degrees of fibrosis, which was the outstanding change. The fibrous tissue showed a varying degree of cellularity in scattered areas. Some portions had only a few elongated nuclei and disintegrated nuclei, others showed an infiltration of round cells and fibroblasts. The tissue contained furthermore, many channels of various sizes lined with endothelium and containing blood cells. Throughout all the sections of the myocardium there was present a moderate amount of lymphocytic infiltration, which appeared to be most marked about the blood vessels. There was no evidence anywhere of fresh infarction. No localized areas of congestion, necrosis or polymorphonuclear infiltration were present. The individual muscle cells showed various stages of degeneration roughly proportionate to the amount of fibrosis surrounding the fibers. In the uninvolved areas the muscle cells appeared normal or sometimes showed hypertrophy of the cells with large hyperchromatic nuclei. The small arteries, except for occasional splitting of the internal elastica, appeared normal.

The right coronary circumflex artery was thickened and markedly calcified throughout its course, and numerous small atheromatous areas were present on the intimal surface. The lumen was completely occluded with organized thrombi in two places. One was immediately at the orifice for a distance of 1 cm and the other was about 5 cm from the orifice also for a distance of 1 cm. The most marked calcification was present in the latter thrombus, which thus appeared to be the older. Beyond the second point of occlusion the changes in the artery were less marked. There were similar pathologic changes in the left coronary artery but they were much greater in degree, so that the left circumflex artery was converted into a solid and calcified cord for its entire course and the left descending artery was similarly involved for a distance of 3 cm about 2 cm from its opening. Beyond this closure the lumen was markedly narrowed, and before the closure no branches were noted arising from the artery. Sections of both arteries revealed evidences of recanalization in the form of occasional lumens, pinpoint to almost pinhead in diameter. In the portions of the arteries that showed a lesser degree of damage there was microscopically present a thinning of the media and a slight degree of fibrosis. In some areas the internal elastica was split, and there was some increase in the subendocardial connective tissue. In the portions more extensively involved there were large areas of calcification and extensive hyalinization involving the entire media. This layer in some places was markedly thinned to almost linear dimensions. The lumen was filled with old thrombi consisting of hyalinized tissue containing vascular channels of various sizes.

The tricuspid, pulmonary and aortic valves grossly were normal. Their rings measured 10, 7 and 6 cm, respectively. The mitral valve was the seat of a marked stenosis producing an orifice only 1 cm in circumference. The cusps were markedly thickened and calcified. No vegetations were present. Microscopically this valve showed the typical reduplication of elastic and fibrous lumens on the auricular surface considered to be characteristic of rheumatic involvement. The same reduplication of layers was present also on the aortic valve on its ventricular surface.

Serial sections were taken of the division of the bundle of His into its two main branches. Nothing more than marked swelling of the Purkinje fibers was found. The adjacent septal musculature showed extensive fibrotic changes separating the muscle fibers into small islands.

COMMENT

The pathologic changes indicate that in this heart with mitral stenosis there had been for several years a progressive atherosclerotic narrowing of the vessels and a series of thromboses leading finally to occlusion of the main coronary arteries, which in turn existed for a fairly long time. That actual infarctions of large areas had taken place at least twice is indicated by the localized areas of fibrosis, one at the base and the other at the apex of the heart. The absence of evidence of a recent thrombosis or a fresh infarction indicates that the heart was able to survive the insult that was the final stroke in occluding all the main coronaries. That the heart apparently was able to compensate fully in the presence of this pathologic condition is one of the most interesting features of this case. The edema disappeared, the liver receded, the patient was up and about for several days without symptoms, and then he walked out of the hospital at a time when the coronaries were solid and calcified cords and a buttonhole mitral stenosis was existing.

Since recanalization of the thrombi was relatively slight and inconstant, only a small amount of blood could reach the capillary bed this way, and other means must be looked for whereby the heart was able to obtain its nutriment. As Pratt¹ suggested the heart may conceivably absorb nutritive elements through its endocardial surface directly from the blood stream, but the nutriment gained this way is necessarily limited. Hudson, Moritz, Wearn and Orgrim² have recently emphasized the rich potentials of the extracardiac coronary anastomoses for compensating for coronary occlusions, especially when extensive pericardial adhesions exist. That a large amount of blood entered the patient's heart in this manner is questionable, since the coronaries were occluded for long distances and no pericardial adhesions existed. Batson and Bellet³ have recently shown that, in coronary occlusion, blood may pass during atrial systole from the atria through the coronary veins directly into the capillaries. With the onset of ventricular systole this blood is forced back to the veins, thus producing a flow and ebb circulation. However, the time periods of the heart cycle, the low mitral pressure and velocity of the venous blood, and the length of the vascular bed of the heart are such that make it very improbable that more than a small quantity of blood can be furnished to the myocardium in this manner. Wearn⁴ and Grant and Viko⁵ have demonstrated in the human heart the extensive ramification of the thebesian vessels, which are small channels connecting coronary veins and capillaries with the chambers of the heart. These vessels have numerous ostia in all four chambers and can transmit blood directly into the capillary bed through many short channels from endocardium to myocardium. Furthermore, in the presence of complete coronary occlusion the thebesian system can act in this regard throughout diastole as long as the intraventricular pressures remain positive. The thebesian vessels bring arterial as well as

venous blood to the capillaries. Wearn⁶ considered the thebesian system the main source of blood supply to the heart in two cases in which the coronary orifices were completely occluded by syphilitic processes. In a heart described recently by Bellet⁷ the large veins as well as the large coronary arteries were completely destroyed by tuberculous myocarditis and the myocardium was nourished through the thebesian vessels.

When one considers that of all the cases of coronary occlusion the one of the very few that survived complete occlusion should be a heart with such a rare combination with mitral stenosis, one realizes that it is unlikely that such a finding is purely a matter of coincidence but that the stenosis possibly plays a beneficial role in coronary occlusion. One of the reasons may be an increased intra-atrial pressure supplying a greater amount of blood through the coronary veins to the capillaries. The prolonged PR interval in this case helped matters in this regard. Another possibility is that the tight mitral stenosis relieved the infarcted or fibrotic left ventricle of some of the strain of the circulation. In experimentally produced mitral stenosis, Katz⁸ described, among other changes, a decrease in the maximum pressure and a marked abbreviation of ejection and systolic time in the left ventricle. Various compensatory mechanisms, however, soon tend to restore conditions to normal. Although it is problematic to what extent the left ventricle is relieved of its normal strain by these changes and their compensatory mechanism in clinical cases of tight mitral stenosis, nevertheless it is not unusual for the left ventricle to be found smaller than normal in these hearts. From these considerations, it might follow that if an individual survives a mitral stenosis long enough to reach the age of coronary occlusion, the former may be an aid to him in combatting the consequences of the latter. The rarity of such combined lesions, however, has prevented statistical studies on this point.

In cases of occlusion of one of the coronary arteries, all the emphasis has been placed on the role played by arterial anastomoses in furnishing blood to the infarcted area, and other mechanisms have received little attention. The importance of the latter in this regard is emphasized in the reported heart, which recovered from its last thrombosis at a time when all interarterial anastomoses could be of little avail. Considering the role the coronary veins play in thrombosis of one of the coronary arteries, during the period of fall of arterial pressure sufficient to permit a reversal of flow in the cardiac veins the heart is in a critical state, and such marked physiologic changes in its circulation would be productive of additional grave dangers. However, the thebesian circulation can theoretically be relegated to a position of great importance in supplying blood to infarcted areas following isolated coronary insults. The anatomic arrangement of the thebesian vessels appears to be such that it can more quickly and effectively furnish blood to an area shut off from the normal supply than can the arterial anastomoses. The thebesian system can bring blood directly to the central portions of the infarcted areas from a very short distance through existing vascular channels, whereas arterial anastomoses must furnish blood from

the borders of the trachea through vascular channels that must take time to form. In cases associated with marked fall of arterial pressure, the thebesian system is in an especially advantageous position in this regard. It may be suggested, furthermore, that the constancy of areas of infarction in certain areas of the heart, i. e., at the apex anteriorly and at the base posteriorly, may possibly be due in some measure to variations in the ramifications of the thebesian system or a diminution in the number of endocardial orifices in these areas, producing a relatively ineffectual thebesian blood supply in these areas. There is no record of anatomic investigations on this point.

Clinical Notes, Suggestions and New Instruments

AN APPARATUS FOR THE EVACUATION OF AIR IN SPONTANEOUS PNEUMOTHORAX

ELLIOTT P. SART, MD, OLIVE VIEW, CALIF.

Spontaneous pneumothorax is a serious accident often leading to death from asphyxia. Usually a complication of pulmonary tuberculosis, especially after artificial pneumothorax has been instituted, it may also result from emphysema, congenital cysts of the lung, or traumatic injuries. It is particularly dangerous when the collapse of the lung is sudden and severe or when a valvelike flap at the site of rupture causes a flow of air from the lung into the pleural cavity but prevents its escape, thus

Apparatus for evacuation of air in spontaneous pneumothorax

building up a positive pressure, and in instances of bilateral pneumothorax, induced or spontaneous. The resulting asphyxia demands the immediate and continued withdrawal of air from the chest. Simple aspiration with an ordinary syringe and needle, or the insertion of a cannula into the chest may avail at times, but repeated or even continuous aspiration is often required. Several such cases developing at the Olive View Sanatorium led to the construction of the apparatus here described which has been found to be both convenient and efficient and has already saved lives.

The apparatus consists of a curved antrum trocar and cannula (Pierce's), which is inserted into the pleural cavity and turned so that its end will not abrade the surface of the lung. The

From the Olive View Sanatorium

cannula is then stitched to the chest wall through its perforated flange, and further sealed at the site of puncture by the application of cotton and collodion, and strapped into place by adhesive tape, which is carried tightly from the spine to the sternum to prevent subcutaneous emphysema from pushing the cannula out. The trocar is then removed from the cannula and an adapter with tubing attached is inserted. A trap and a cotton filter are interposed between the cannula and a rubber bulb, which is fitted with valves allowing the air to flow in one direction only, outward. An ordinary atomizer bulb, with its connections reversed may be used for this purpose. A glass tubing connects with a manometer which can be shut off when the readings are not being taken.

The rubber bulb is placed within the patient's reach and he is instructed how to read the manometer and how to work the bulb whenever the positive pressure becomes too high or when he feels short of breath. In this way subcutaneous emphysema and impairment of respiration from excessive collapse of the lung or displacement of the mediastinum can be kept under control, pleural effusions that develop may be removed (none have been experienced to date), and either neutral or slight positive pressure maintained, facilitating an early closure of the ruptured lung. In actual practice it has proved to be a great therapeutic aid to the physician as well as a great relief to the patient, who gains confidence and security from the knowledge that he can control the situation himself.

THE PREVENTION OF DIPHTHERIA AND SCARLET FEVER IN NURSES

LUDVIG HEKTOEN, MD, AND CHARLOTTE JOHNSON, RN, CHICAGO

Our purpose in this note is to complete the records of the prevention of diphtheria and scarlet fever among the nurses in the Durand Hospital, which was closed, at least temporarily, at the beginning of this year. Since the opening of the hospital in March, 1913, special efforts have been made to protect the nurses against the infectious diseases with which they were dealing and especially diphtheria and scarlet fever. As tests for susceptibility and immunization of susceptibles developed, these methods were applied to the nurses. Accurate records of the health of the nurses while in the hospital have been kept. The capacity of the hospital was sixty beds. Only patients with acute infectious diseases (mostly diphtheria and scarlet fever) were received. At first the nursing was done principally by graduate nurses but after the end of the second year the bedside nursing was in the hands of student nurses working under the direction of trained supervisors. Nearly all the student nurses came to the hospital for three months from other hospitals in Chicago and vicinity. They were in no sense seasoned nurses but mostly recent arrivals in Chicago, the age varied from 19 to 35 years, the average being about 23. Special care was taken to maintain a high degree of cleanliness of patients and surroundings, from the start the nursing procedure was organized precisely and supervised rigidly to prevent as much as possible the spread of infectious materials. The health of each nurse was watched closely, nose and throat cultures were made regularly each week. The general conditions under which the nurses lived and worked did not change in any marked degree during the period in question. During this period, 3,673 cases of diphtheria and 5,416 cases of scarlet fever were treated in the hospital under the direction of Dr. George H. Weaver. Except as determined by chance, each student nurse came into equally close contact with diphtheria and scarlet fever patients. Selective or exclusive assignments of the nurses were not made. In 1928 a report¹ was published on the incidence of diphtheria and scarlet fever among these nurses up to Dec. 1, 1927. That report gives in detail the rules and suggestions for the protection of nurses and others. Practically the only difference between that report and this is that now the figures for the period after Dec. 1, 1928, have been added. Table 1 shows that of 349 nurses originally insusceptible (negative Schick test), six developed diphtheria, that of these 349 insusceptibles the 192 in the period 1921 to

the closing of the hospital did not have a single case of diphtheria, that of 397 susceptibles (positive Schick test) immunized to negative Schick test before entering on duty, one had diphtheria, and that of all the nurses in this tested and immunized group, 802 in all, 7, or 0.89 per cent, had diphtheria. It should be pointed out that no cases of diphtheria have developed among the nurses since Dec 1 1927. Table 2 shows that before the Dick test and the preventive injection of toxin the percentage of scarlet fever among the nurses (516) was 7.7, that of 309 nurses who began their work as originally suscep-

ceptible (Dick negative), no one came down with scarlet fever, that of 200 susceptibles (Dick positive) immunized to Dick negative before going on duty, no one developed scarlet fever and that of the 614 nurses taken into service since the Dick test came in use, 3, or 0.50 per cent, had scarlet fever. Again it is noteworthy that no cases of scarlet fever have developed in the nurses since Dec 1, 1927.

The observations on the student nurses in the Durand Hospital establish that naturally Schick negative and Dick negative young women are well protected against diphtheria and scarlet

TABLE 2—Scarlet Fever in Student Nurses in the Durand Hospital

	Number of Nurses	Cases of Scarlet Fever	
		Number	Per Cent
Before Dick test (March 12 1912 to Dec 31 1921)	516	40	7.7
After Dick test (Jan 1 1924 to Jan 28 1933)			
Originally Insusceptible	309	0

fever. Further, that susceptible young women immunized to negative Schick and Dick tests before assuming the active nursing of diphtheria and scarlet fever patients are also well protected.² As stated in the former report,¹ "by means of Schick and Dick tests followed, when necessary, with active immunization, nurses can be selected who are practically free from the danger of diphtheria and scarlet fever."

637 South Wood Street

² The results are corroborated by the work of Rhoads on the prevention of diphtheria and scarlet fever in the nurses in the Cook County Hospital Chicago (Rhoads P. S. Skin Tests and Immunization Against Scarlet Fever and Diphtheria J. A. M. A. 97 153 [July 18] 1931)

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER Secretary

ACCEPTANCE OF SUNLAMPS

During the past seven years the Council on Physical Therapy has devoted much time and effort to the question of ultraviolet radiation therapy, and in two preliminary statements¹ gave its conclusions and its specifications for acceptance of "sunlamps," by which term is understood a lamp that, at a specified distance, emits ultraviolet radiation not differing essentially from that of the clearest weather midday, midsummer, midlatitude, sea level, natural sunlight in total intensity and in spectral range of wavelengths extending from about 2,900 to and including 3,130 angstroms and that does not emit an appreciable amount of ultraviolet radiation of wavelengths shorter than 2,800 angstroms.

Sunlamps so called, are not to be confused with therapeutic ultraviolet generators designed for service in hospitals, clinics and offices of physicians. Since sunlamps are for unsupervised home use they are often of low intensity to avoid injury from overdosage.

After extensive investigation and inquiry, in collaboration with physicists and other scientists acting as consultants, and after due consideration of the status of ultraviolet radiation therapy the Council on Physical Therapy has adopted, and until a more practicable and reliable procedure is proposed, will use the erythematous reaction as a basis for judging the effectiveness of a sunlamp for the following reasons:

(a) The erythematous response is in common use as an indicator of skin tolerance and of the amount of ultraviolet radiation that can be applied at one time and so long as the present-day types of ultraviolet generators are used the erythematous test will be necessary to prevent injury from burns.

(b) It is practically the only physiologic reaction to ultraviolet rays that is established with a relatively high degree of accuracy, permitting a calculation of the approximate time of exposure from a simple physical measurement of the ultraviolet radiant flux emitted by the lamp.

(c) It is a simple and practicable means of preventing severe burns when using powerful sources of ultraviolet radiation.

(d) It is an efficient safeguard against the fraudulent sale of lamps that emit little or no radiation of wavelengths shorter than about 3,130 angstroms, generally accepted as having a specific therapeutic value in preventing rickets.

In an adopted article entitled "Ultraviolet Radiation Useful for Therapeutic Purposes—Specification of Minimum Intensity or Radiant Flux," by Dr. W. W. Coblentz, the Council has definitely specified the types of ultraviolet radiation generators that possess sufficient ultraviolet energy to be of therapeutic value. Furthermore, the Council has drafted two lists of requirements to govern advertising of ultraviolet generators to the public and to the profession.²

The Council's specifications of minimum intensity are based on a comfortable and convenient operating distance (namely 24 inches, or 61 cm.) from the front edge of the reflector, at which distance the exposure can be made without burning the skin. The ultraviolet intensity of the lamp shall be such that the time of exposure to obtain a minimum perceptible erythema (if such a dose is desired) is sixty minutes or a total of 120 minutes for a complete exposure front and back. In this connection it is relevant to note that the Council does not prescribe the dosage of ultraviolet radiation. Its function is to advise and protect the medical profession and the public against misleading and deceptive advertising in connection with the manufacture and sale of devices for use in physical therapy.

¹ Acceptance of Sunlamps. A Preliminary Statement J. A. M. A. 99 31 (July 2) 1932 100 1863 (June) 1933. The present specifications for acceptance of sunlamps supersede the earlier statements on this subject.

² Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession Only and Regulations to Govern Advertising of Ultraviolet Generators to the Public Only J. A. M. A. 98 400 (Jan 30) 1932.

In view of the increasing number of so called sunlamps, some emitting so little ultraviolet that from ten to twenty hours would be required to obtain an erythematous dose, the purchaser of a sunlamp has a right to expect and the Council on Physical Therapy requires the ultraviolet output to be sufficiently strong, relative to the total heat emanating from the lamp that, if an erythematous dose is desired in fifteen minutes, the operating distance can be shortened without burning the bare skin by the heat ("heat burn") of the lamp in its reflector.

Physiologic experiments show that for practical purposes the wavelength of maximum erythemogenic action may be taken at the emission line of homogeneous radiation of mercury vapor, at 2967 angstroms, present in many sources of ultraviolet radiation. The erythemogenic efficiency of this emission line is practically 100 per cent. No other wavelength or group of wavelengths, in any source, has such a high efficiency in generating an erythema.

For example, the erythemogenic efficiency (these values are subject to slight revision when better known) of the ultraviolet of wavelengths shorter than and including 3130 angstroms in sea level, midlatitude noonday June sunlight, is about 0.22 (22 per cent), the Mazda type S-1 Lamp, 0.24, the Mazda type S-2 Lamp, 0.215, the low temperature, type G, mercury vapor glow lamp, 0.185, the so called cold quartz, low temperature low vapor pressure, mercury arc, 0.55, the high temperature, high vapor pressure quartz mercury arc 0.344, the high frequency, electrodeless discharge, quartz mercury arc 0.33, the blue flame carbon arc lamp 0.42 and the Mazda CX tungsten filament lamp, from 0.16 to 0.20, depending on the temperature of the filament.

The intensity and the erythemogenic action of the emission line of mercury at 2967 angstroms is easily evaluated in absolute units, and the erythemogenic action, as well as the radiometric output of heterogeneous ultraviolet radiation from various sources is easily correlated with this emission line as a standard.

The Council has therefore adopted 10 microwatts per square centimeter of homogeneous radiation of wavelength 2967 angstroms as the unit of intensity of erythematous flux, and has (tentatively) called it the Einsen unit³ (ΓU), that is $1 \Gamma U = 10$ microwatts per square centimeter of wavelength 2967 angstroms. On the basis of the Council's specification of an exposure of fifteen minutes, it will require 20 microwatts per square centimeter (2 ΓU) of homogeneous radiation of wavelength 2967 angstroms to produce a minimum perceptible erythema. The amount of ultraviolet radiation of wavelengths shorter than and including 3130 angstroms that a source must emit, equivalent to 20 microwatts per square centimeter of homogeneous radiation of wavelength 2967 angstroms, is obtained by dividing the 20 microwatts by the erythemogenic efficiency of the source in question. For example, the erythemogenic equivalent of standard sunlight is $(20 \div 0.22 =) 91$ microwatts per square centimeter, and for the type G mercury vapor glow lamp it is $(20 \div 0.185 =) 108$ microwatts per square centimeter.

The erythemogenic efficiency of a source is obtained by the method employed at the Bureau of Standards,⁴ using the revised spectral erythemal response curve of the average untanned skin.⁵

From the foregoing specifications, it follows that in order to produce a minimum perceptible erythema on the average skin, in fifteen minutes for therapeutic lamps and in sixty minutes for so called sunlamps, the erythemogenic equivalent of the heterogeneous ultraviolet radiant flux of wavelengths shorter than and including 3130 angstroms, emitted by the various sources mentioned shall not be less than the values given in the accompanying table (Erythematous Unit, E U).

The specification of minimum acceptable intensities given in the table are average values observed in a 0-5° zone subtended by the center of the source (burning at an angle, if so used in practice), i. e., within a circle approximately 4 inches (10 cm)

in diameter, lying in a plane at right angles to the axis of the reflector, at the specified operating distance.

To avoid burns, the irradiated area shall be free from "hot spots," having an intensity greater than two times the average value measured in the central 0-5° zone, free from "hot spots."

At no point within a circle about 18 inches (45 cm) in diameter, at a distance of 24 inches (61 cm) from the front edge of the reflector (more specifically, in a 0-20° zone, subtended by the center of the source and lying in a plane at right angles to the axis of the reflector) shall the intensity be less than one-third the average value observed in the central 0-5° zone. Since a circle 45 cm in diameter contains about 1,600 cm² (if it were uniformly irradiated with 1 ΓU per square centimeter) the total erythematous flux would amount to about 16,000 microwatts. In practice, this area cannot be irradiated uniformly, hence it is necessary to take this fact into consideration.

The correlation of erythemogenic equivalents of the various lamps, given in the table is to be used in the following manner. Suppose, for example, that a type G mercury vapor glow lamp

Minimum Acceptable Intensities

1 ΓU	= 20 microwatts per sq cm of homogeneous radiation of wavelength 2967 angstroms exposure 15 minutes
= 5 microwatts per sq cm of homogeneous radiation of wavelength 2967 angstroms exposure 60 minutes	
= 91 microwatts per sq cm of midday, midsummer midlatitude sea level ultraviolet solar radiation exposure 15 minutes	
= 23 microwatts per sq cm of midday midsummer, midlatitude sea level ultraviolet solar radiation exposure 60 minutes	
= 83 microwatts per sq cm of Mazda type S 1 lamp radiation, exposure 15 minutes	
= 21 microwatts per sq cm of Mazda type S 1 lamp radiation exposure, 60 minutes	
= 93 microwatts per sq cm of Mazda type S 2 lamp radiation, exposure 15 minutes	
= 23 microwatts per sq cm of Mazda type S 2 lamp radiation exposure 60 minutes	
= 108 microwatts per sq cm of low temperature type G mercury vapor glow lamp radiation exposure 15 minutes	
= 27 microwatts per sq cm of low temperature type G mercury vapor glow lamp radiation exposure 60 minutes	
= 58 microwatts per sq cm of high temperature high vapor pressure quartz mercury arc radiation, exposure 15 minutes	
= 14.5 microwatts per sq cm of high temperature high vapor pressure quartz mercury arc radiation exposure 60 minutes	
= 60 microwatts per sq cm of high frequency electrodeless discharge mercury arc radiation in a quartz bulb exposure 15 minutes	
= 15 microwatts per sq cm of high frequency electrodeless discharge mercury arc radiation in a quartz bulb exposure 60 minutes	
= 36 microwatts per sq cm of cold quartz low temperature low vapor pressure quartz mercury arc radiation exposure 15 minutes	
= 9 microwatts per sq cm of cold quartz low temperature low vapor pressure quartz mercury arc radiation exposure, 60 minutes	
= 48 microwatts per sq cm of blue flame carbon arc lamp radiation (in reflector no filter window) exposure, 15 minutes	
= 12 microwatts per sq cm of blue flame carbon arc lamp radiation (in reflector no filter window) exposure 60 minutes	

is submitted to the Council for acceptance and that the radiometric measurements at 24 inches (61 cm) indicate an ultraviolet radiant flux of 9 microwatts per square centimeter. Since this is only $(9 \div 27 =)$ one third of the minimum requirement for this type of sunlamp, it will be necessary to prolong the exposure for $(3 \times 60 =)$ 180 minutes (3 hours) if it is desired to obtain an erythematous dose with the lamp at 24 inches. Obviously, such a lamp does not comply with the Council's specifications.

In the low temperature glow lamps, which have a low infra-red output, it may not be found objectionable to shorten the operating distance in order to shorten the time of exposure. On the other hand, in the case of the tungsten filament lamp, the large amount of heat from the filament and from the glass bulb may become intolerable when the lamp is operated close to the body.

From time to time, acceptances or rejections of sunlamps for home use will be published in the columns of the Council on Physical Therapy in *THE JOURNAL*. In accepting sunlamps the attention of the profession is called to the following:

A. The Council on Physical Therapy definitely withholds acceptance of the postulatory principle of dual-purpose lighting,

³ Coblenz W W. Ultraviolet Radiation Useful for Therapeutic Purposes. J A M A 98 1082 (March 26) 99 125 (July 9) 1932. Luckiesh M and Holladay L L. Fundamental Units and Terms for Biologically Effective Radiation. J Opt Soc America 23 197 (June) 1933.

⁴ Coblenz W W. Stair R and Hogue J M. Bur Sids J Research 8 770 (June) 1932. Res Paper 450 obtainable only from the Supt of Documents Washington D C price 5 cts.

⁵ Coblenz W W. Stair R and Hogue J M. Bur Sids J Research 8 541 (April) 1932. Res Paper 433 price 5 cts revised data in Res Paper 631 January 1934.

because it is highly theoretical and the promulgators of this idea have not presented acceptable clinical evidence to the Council substantiating its therapeutic or prophylactic value.

B The Council on Physical Therapy declines to accept sunlamps if the manufacturer fails to state in all advertising matter and descriptive literature the distance between the lamp and the recipient required to equal the intensity of midday, midsummer, midlatitude, sea level, natural sunlight. Thus, in the acceptances that follow, the reader will note that the manufacturer has stated the distance the recipient should be from the sunlamp to receive the alleged benefits.

C The manufacturers of acceptable sunlamps for home use have agreed to discontinue objectionable claims, such as that exposure to ultraviolet rays increases or improves the tone of the tissues or of the body as a whole, stimulates metabolism, acts as a tonic, increases mental activity, maintains health or tends to prevent colds, because these claims have not been conclusively substantiated by experimental evidence.

D The Council declines to sanction claims recorded in descriptive literature and advertising matter in which implication is made that the production of an erythema is unnecessary as a test of intensity, that suberythema doses are sufficient for therapeutic benefit. The Council believes that, while such statements may be made in good faith, they merely open the way to fraud by irresponsible vendors of alleged sources of ultraviolet radiation. Until further evidence is presented to prove otherwise, the Council declares that the erythema test is the only means of determining whether appreciable ultraviolet is emitted by the source.

In order that there can be no misunderstanding on the part of any one relative to the stand of the Council on Physical Therapy on the acceptance of sunlamps, the dual-purpose lighting and the suberythema dosage, the aforementioned stipulations are given to the profession that it may better understand the problems confronting the Council regarding ultraviolet radiation therapy. The Council will give careful consideration to clinical evidence scientifically gathered by controlled experiments.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

ANTIMENINGOCOCCUS SERUM (See New and Nonofficial Remedies, 1933, p 367)

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore

Antimeningococcic Serum (See New and Nonofficial Remedies 1933 p 368)

Also marketed in one syringe containing 30 cc with intraspinal and intravenous injection outfit

SODIUM AMYTAL (See New and Nonofficial Remedies, 1933, p 99)

The following dosage forms have been accepted

Ampoule Sodium Amytal 0.125 Gm (1½ grains)

Pulverules Sodium Amytal 1 grain

MEAD'S HALIBUT LIVER OIL WITH VIOSTEROL 250 D (THE JOURNAL, Nov 18, 1933, p 1634)

The following dosage form has been accepted

Mead's Vioesterol in Halibut Liver Oil 250 D (In Capsules) Each capsule contains 3 minims of Mead's vioesterol in halibut liver oil 250 D representing a vitamin potency of not less than 5,500 units of vitamin A (U. S. P. X) and 570 units of vitamin D (Steenbock)

LUMINAL-SODIUM (See New and Nonofficial Remedies, 1933, p 99)

The following dosage form has been accepted

Ampules Luminal Sodium Solution in Ethylene Glycol 2 cc Each cubic centimeter contains luminal sodium 2.5 grains dissolved in ethylene glycol. The solution may be administered intramuscularly or subcutaneously but not intravenously

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEECH, Secretary

VINYL ETHER

Vinyl ether (divinyl ether, divinyl oxide) is a preparation of Merck & Company, Inc., originally proposed by Leake and Chen¹ for use in inhalation anesthesia in place of ethyl ether and subsequently studied by Leake and his co-workers,² by Gelfan and Bell,³ and by Goldschmidt, Ravdin, Lucke, Muller, Johnston and Ruigh,⁴ whose paper appears in this issue.

At the request of the Council on Scientific Assembly, the Council considered the available evidence as to the therapeutic usefulness of vinyl ether previous to the annual session of the American Medical Association in order that Dr Ravdin and his associates might present their observations at a section of the assembly at Milwaukee. The Council authorized publication of the following report.

Vinyl ether ($\text{CH}=\text{CH}-\text{O}-\text{CH}=\text{CH}$) was prepared in pure form by Ruigh and Major⁵ of the Merck Laboratory of Pure Research, in 1930. It is a highly volatile liquid (boiling point 28.3°C), having a peculiar sweetish ethereal odor somewhat reminiscent of that of ethylene ($\text{CH}_2=\text{CH}_2$), to which substance it is closely related chemically, it is more inflammable than ether and is relatively unstable in the chemically pure state, forming resin-like polymers, and decomposing with the development of formaldehyde and formic acid, in the presence of light and air, it is readily decomposed by traces of acid.

Vinyl ether, as prepared for anesthesia, is said to contain 0.01 per cent phenyl-alpha-naphthylamine to prevent polymerization and decomposition, and 3.5 per cent absolute ethyl alcohol to prevent freezing on evaporation. This product is not yet marketed for general use and is prepared at present only for investigative work.

The advantages claimed for vinyl ether over ethyl ether are that it is less irritating to mucous membranes, that induction of anesthesia is much more rapid and recovery much more prompt resembling ethylene in the latter respects, that it has a somewhat higher partition coefficient than ethyl ether, that the minimum anesthetic concentration is much lower, that the minimum blood concentration of vinyl ether necessary for anesthesia is about one-fourth that of ethyl ether, that vinyl ether offers a greater margin of safety.

According to Goldschmidt and his co-workers, in normal dogs the critical period for the production of liver necrosis appears to lie between two and three hours of anesthesia with vinyl ether. In a series of monkeys two three hour periods, and in one case a six hour period of anesthesia did not result in liver necrosis.

Clinically, vinyl ether has been used for short periods in three individuals by Gelfan and Bell, and in 428 patients in the series of Goldschmidt et al. Induction is said to be exceedingly rapid and recovery correspondingly prompt, the latter occurring frequently in from thirty seconds to one minute. Satisfactory surgical relaxation is stated to obtain and anesthesia has been maintained for varying periods up to nearly three hours. Postoperative emesis is said to have occurred in 12.8 per cent of the patients in the series of Goldschmidt and his collaborators. No evidence of injury to the liver or kidneys was seen in any case in that series.

The Council decided to defer further consideration of Vinyl Ether for Anesthesia pending accumulation of additional evidence as to the therapeutic usefulness of this product and until the manufacturer markets vinyl ether for general use, at that time the preparation will also be examined by the A. M. A. Chemical Laboratory.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CARTOSE A CARBOHYDRATE SYRUP FOR INFANT FEEDING

Distributor—Scientific Sugars Company, Indianapolis
Manufacturer—Union Starch and Refining Company, Granite City, Ill

Description—Syrup consisting essentially of maltose, dextrins, dextrose and sucrose

Manufacture—Glucose or corn syrup (90 parts) prepared as described for Pennant Crystal White Syrup (THE JOURNAL, Jan 30, 1932, p 402) and light brown sugar (10 parts) are mixed in a glass lined autoclave and adjusted to 75 per cent solids content. The mixture is raised to a temperature of 121 C, cooled to 82 C and filtered through 100 mesh cloth into glass bottles in a room supplied with filtered air. The bottles are capped in a steam chamber.

Analysis (submitted by manufacturer) —

	per cent
Moisture	25
Ash	0.4
Protein (N X 6.25)	0.1
Sucrose	7.0
Reducing sugars as invert sugar	0.5
*Maltose	30
*Dextrose	12
*Dextrins	25

(The analysis is calculated from separate analyses of the ingredients corn syrup and brown sugar.)

*Feitzer, Evans and Longenecker, *Indust. & Engin. Chem. anal. ed.* 5, 81, 1933.

Calories—30 per gram 85 per ounce 123 per fluidounce

Claims of Manufacturer—A carbohydrate syrup recommended as a carbohydrate supplement for milk modification in infant feeding. The method of preparation and packing assure absence of pathogenic organisms.

CAPITOL BRAND EVAPORATED MILK

Packer—John F. Jelke Company, Hillsboro, Wis

Description—Canned unsweetened sterilized evaporated milk, the same as Jelke Good Luck Evaporated Milk Unsweetened, Sterilized (THE JOURNAL, July 29, 1933, p 367).

BEECH-NUT STRAINED PRUNES

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved prunes retaining in high degree the natural vitamin and mineral values.

Manufacture—California prunes are soaked over night washed, allowed to simmer in open kettles with a small amount of water for one hour, pitted, strained and subsequently treated as described for Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562). The jars are processed at 100 C for thirty minutes.

Analysis (submitted by manufacturer) —

	per cent
Moisture	69.5
Total solids	30.5
Ash	0.7
Fat (ether extract)	0.2
Protein (N X 6.25)	0.1
Reducing sugar as invert sugar	20.9
Sucrose (copper reduction method)	0.0
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	28.9

Calories—12 per gram 34 per ounce

Vitamins and Claims of Manufacturer—See these sections for Beech Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562).

IRRADIATED VITAMIN D PASTEURIZED MILK

Distributor—Gridley Dairy Company, Inc., Milwaukee (subsidiary of The Borden Company, New York)

Description—Bottled pasteurized vitamin D milk irradiated by Steenbock process (patent No. 1,680,818).

Preparation—Milk is irradiated by a "CP Carbon Arc Lamp Milk Irradiator" equipped with recording meters for measuring lamp energy input, output of milk pump, and ultraviolet ray emanations of the arc lamps, which provide complete charts of operation for inspection by plant and health officials. The irradiated milk is pasteurized by standard procedure (holding method thirty minutes at 63 C), immediately cooled, automatically bottled and capped.

Vitamins—Clinical investigation shows this irradiated milk to be a reliable antirachitic agent protecting practically all infants excepting those prematurely born, contains 50 Steenbock vitamin D units per quart.

Claims of Distributor—Irradiated antirachitic pasteurized milk having otherwise the natural flavor and food values of usual pasteurized milk. Complies with the requirements of the state of Wisconsin and the health department of the city of Milwaukee. The method of irradiation and the equipment are under scientific control.

COLLEGE INN TOMATO JUICE COCKTAIL

Distributor—College Inn Food Products Company, Chicago

Packer—Welch Grape Juice Company, North East, Pa.

Description—Tomato juice cocktail containing tomato juice, Worcestershire sauce and salt, retaining in high degree the vitamin content of tomatoes.

Manufacture—Essentially the same as for College Inn Pure Tomato Juice (THE JOURNAL, Dec 23, 1933, p 2051) with the exception that Worcestershire sauce is added and the final processing of the jars is for twenty minutes at 82 C.

Analysis (submitted by manufacturer) —

	per cent
Moisture	91.7
Total solids	8.3
Ash	1.4
Sodium chloride	1.0
Fat (ether extract)	0.0
Protein (N X 6.25)	0.6
Reducing sugars as invert sugar	4.1
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	5.6
Titratable acidity as citric acid	0.5

Calories—0.3 per gram 8 per ounce

Vitamins and Claims of Manufacturer—See these sections for College Inn Pure Tomato Juice (THE JOURNAL, Dec 23, 1933, p 2051).

ANITA HIGH PROTEIN FLOUR

(BLEACHED AND UNBLEACHED)

ESTRELLA FLOUR

(BLEACHED AND UNBLEACHED)

Manufacturer—Texas Star Flour Mills, Galveston, Texas

Description—Hard red winter wheat "straight" flour, bleached and unbleached.

Manufacture—Selected hard red winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. All flour streams are blended and are bleached with nitrogen trichloride (one-ninth ounce per 196 pounds) and with a mixture of calcium phosphate and benzoyl peroxide (1 part to 50,000 parts of flour).

Claims of Manufacturer—For general baking.

I G A CRYSTAL TABLE SYRUP

(CORN SYRUP FLAVORED WITH CANE SUGAR SYRUP)

Packer—Wheeler-Barnes Company, Minneapolis

Distributor—Independent Grocers Alliance Distributing Company, Chicago

Description—Table syrup, corn syrup base (85 per cent) with cane sugar syrup (15 per cent), the same as White Oak Brand Crystal White Syrup (THE JOURNAL, Oct 15, 1932, p 1353).

MORE CRYSTALLINE ENZYMES

Biology and medicine have been interested for a century in the existence of substances that possess the unique property of biochemical catalysts. Recently, reference was made¹ to the centenary of the introduction of the word "diastase" by Payen and Persoz to represent the constituent of barley malt that converts starch into sugar, just as strong acids do, although no living cells are present. Until recently the French writers have in fact called all enzymes "diastases," though this word has been all but abandoned in the English literature of biochemistry. During the past hundred years many biochemical catalysts, sometimes designated as "unorganized ferments" and more commonly as "enzymes," have been described. They abound in the digestive secretions, where they play an important part in alimentation. They occur in plant tissues and in micro-organisms.

The preparation of a substance in crystalline form is usually accepted as evidence that it has been obtained in a condition of relative purity. Recrystallization increases the degree of purity. To Prof J B Sumner of Cornell University goes the credit of having first described, in 1926, the crystallization of an enzyme, urease, that promotes the conversion of urea to ammonia and carbon dioxide. Since then science has witnessed the description of crystalline pepsin, amylase and trypsin in this country. All these products have the properties of proteins. Some of the European biochemists have alleged that the crystalline proteins are not themselves the functional catalysts but are merely the "carriers" of the active groups. This implies, according to the view of Willstätter, that the intrinsic part of an enzyme is some specifically active radical anchored to a carrier which is characterized by high molecular weight but is not necessarily markedly specific in character. American investigators are inclined to debate this distinction.

The most recent contribution comes from the Rockefeller Institute for Medical Research in Princeton,

N J, through Kunitz and Northrop,² who already have achieved merit in the preparation of crystalline pepsin and trypsin. It has been known, through the classic studies of Kuhne at Heidelberg and Heidenhain at Breslau, that the proteolytic enzymes of the pancreas are completely inactive in fresh pancreas or in freshly secreted pancreatic juice. The enzymes become active when mixed with the enterokinase of the small intestine, as found by Schepowalnikow, or when the pancreas is allowed to stand in slightly acid solution. According to Vernon, activation may also be brought about by small amounts of active trypsin. The mechanism of this activation has been the subject of controversy for many years. Kunitz and Northrop have now described the isolation from fresh pancreas of an active crystalline protein which is converted by minute amounts of trypsin into a powerful proteolytic enzyme. This enzyme also has been obtained in crystalline form. The inactive protein has been called chymotrypsinogen and the active protein chymotrypsin. The activity of this preparation is about one-third that of the previously described crystalline trypsin with respect to the digestion of hemoglobin or casein. It is much less active than trypsin in liquefaction of gelatin but much more active in clotting milk. It does not clot blood and contains no amylase or lipase activity. The digestion of casein is carried much further than by the crystalline trypsin. The enzyme is evidently quite distinct from the trypsin previously isolated and may represent the "pancreatic rennet" of Vernon. The chymotrypsinogen has been recrystallized ten times and shows constant optical activity and constant proteolytic activity after activation by trypsin. Kunitz and Northrop have reason to believe that these new preparations represent pure proteins and that the proteolytic activity is a property of the protein molecule. Another distinguished achievement of American research effort has thus become recorded.

NUTRITION IN NATIONAL EMERGENCIES

Regardless of whether the situation is due to pestilence, war or economic distress, through which many nations have been passing in recent months, the most pressing problem that is likely to confront governments in such critical times is that of an adequate food supply for all classes of society. The realization of this was awakened to an unprecedented degree during the World War. In 1917 Herbert Hoover, at that time United States food administrator, pointed out¹ that the great conflict had entered a phase in which food dominated the economics, strategy and statesmanship not only of the countries at war but of neutrals as well. The Allies were blockading Germany, and its population was living in an era of food control previously undreamed of.

² Kunitz M and Northrop J H. Isolation of a Crystalline Protein from Pancreas and Its Conversion into a New Crystalline Proteolytic Enzyme by Trypsin. *Science* 78: 558 (Dec 15) 1933.

¹ Kellogg V L and Taylor A E. *The Food Problem*. New York: Macmillan Company, 1917. preface.

¹ The Centenary of the Discovery of Diastase. editorial J A M A 201: 1564 (Nov 11) 1933.

The adjacent neutrals were under many restraints and pressures to yield their food to either side and were striving with every resource to protect their vital supplies. The Germans were trying to starve the Allies by sinking their supplies at sea. All were desperately trying to maintain production and reduce consumption. In consequence, food problems in balancing vegetable and animal production, in imports, exports and price controls, in protein, fat and carbohydrate content, were all silhouetted against a background of destruction and tragedy.

Under such ominous conditions, some of the leading nutrition experts in each country were called on to offer suggestions that might help to meet desperate situations. One American enthusiast ventured the public statement that "ours is the splendid burden of feeding the world." Within recent years the irony of fate has brought to our nation the necessity of giving serious attention anew to the problems of national nutrition. An almost unprecedented trade depression with millions of unemployed and poorly paid workers has presented the threat of undernutrition and malnutrition among our citizens. Almost every state in the Union, in addition to various federal government agencies, has organized scientific and philanthropic forces to avert nutritional disasters. The outcome of some of these deliberations and activities has been reviewed in earlier issues of *THE JOURNAL*.² Such undertakings have done far more than to meet impending emergencies, they have helped to summarize and apply the prevailing knowledge of nutrition at a period when notable advances were being reported in this science. This is true particularly of the growing information about vitamins and essential inorganic components of the diet.

Some time ago the British Medical Association appointed a Committee on Nutrition, which has recently published its report.³ There was said to be on the one hand a considerable body of opinion that malnutrition is not observable among the poor, and on the other hand that it exists to a considerable extent. The British committee was specifically instructed "to determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size if health and working capacity are to be maintained, and to construct specimen diets."

As in all such cases, it became necessary first of all to define the nature of the various essential constituents of a diet that would fulfil the requirements, and, further, to agree on the quantities necessary at varying ages. The task is not an easy one, as the requisite food intake must be varied with the amount of physical labor involved and the number of children of different ages in the families to be supported, as well as the availability and comparative costs of different common foods. Allowance must also be made for wastage in their preparation

and alimentary utilization. The British committee, after careful consideration, recommended the adoption of the figure 3,400 calories in the food as purchased as the unit requirement of the normal man of average stature, if health and working capacity are to be maintained. This is not regarded as a minimum figure, nor would the adoption of a bare subsistence standard fulfil the terms of reference of the committee, which specifically states that both health and working capacity are to be maintained. It, moreover, does allow a little latitude for individual variation.

It is interesting to compare this conclusion with the deliberations of the experts at work during the World War. The Interallied Scientific Food Commission, which met in Paris late in March, 1918, adopted the following resolution: "That the requirements of the average man of 70 kilograms body weight doing eight hours average physical work in a climate such as England's or France's is to be considered as 3,300 calories as purchased." It was decided that 3,000 available calories as ingested was the requirement of the average man leaving a 10 per cent margin for domestic spoilage or waste.⁴ In the provision of the "emergency" rations in this country in recent months, the tendency has been toward a limitation of the provision of energy to somewhat less than 3,000 calories a day for the average adult man. Fractional requirements for persons of varying size and age have repeatedly been published.

The British experts have taken a noteworthy stand with respect to the protein factor in nutrition. Thus, they state,

It is now usual to differentiate the protein foodstuffs into two classes. Proteins from animal sources are designated as first-class proteins, whilst those of vegetable origin are relegated to the second class. The first-class proteins, besides possessing a higher nutritional value than second-class proteins, are more nearly completely absorbed by the body. Vegetable proteins are absorbed in varying proportions, which rarely exceed 80 per cent. There is a measure of agreement that from 10 to 15 per cent of the daily calories should be derived from protein, and 100 grams of protein per day will provide 12 per cent of the total daily calory supply of 3,400. The Committee agrees that 50 grams of first-class protein per day is sufficient to maintain the health and working capacity of the average man. The figure of 50 grams of first-class protein represents half the daily protein intake. The other half can be furnished from vegetable sources.

This conclusion will scarcely please the advocates of the exclusive vegetarian diet, though it will not affect those who practice the more common forms of lacto-vegetarianism.

The new report alleges that a common fault in the dietaries of young children is a shortage of first-class protein. It insists that the popular prejudice against giving meat and cheese to children of this age is not based on physiologic data. In Britain, as in this country, the general consensus on the value of milk as a food for young children is so strong that it should be included in every case in the diet of children in order

² Food and Nutrition in the Depression Period editorial J. A. M. A 98: 50 (Jan. 2) 1932. Depression Death Rates *ibid* 99: 1354 (Oct. 15) 1932. Malnutrition in Children *ibid* 101: 1318 (Oct. 21) 1933.

to maintain health and normal growth. The American tendency would be, however, to exceed somewhat the guiding rule of 1 pint of milk a day for a child up to the age of 5 and of half a pint of milk from 5 years to 10. The usual stress is placed on the invariable inclusion of dairy produce, fruits and green vegetables in the family diet in order to ensure a sufficiency of food containing vitamins and mineral constituents. In view of rapidly changing purchasing values it is almost futile to compare the proposed costs of adequate nutrition in times of stress. It is heartening, however, to find such general agreement among the English-speaking nations in respect to the fundamental food problems of their people.

Current Comment

BOVINE TUBERCULOSIS

Many years ago, extensive investigations in this country and abroad proved that the organism causing tuberculosis in cattle is capable of infecting human beings. Bovine tuberculosis rarely causes pulmonary tuberculosis in adults, but according to Park and Krumwiede,¹ the bovine bacillus causes about one tenth of the bone joint and lymph node tuberculosis in adults and one fourth of this type of tuberculosis in children. In young children it is said to cause from $6\frac{1}{3}$ to 10 per cent of the total fatalities from this disease. Tuberculosis in cattle is beyond question, a menace to public health. How the infection in cattle reaches man is another problem that has been extensively studied and it is agreed that the chief agent in transmitting the infection is cow's milk. The well known process of pasteurization if properly done will destroy the tubercle bacilli in milk. But pasteurization is not always properly done and it is not everywhere required to be done at all. Strange to say, there are interests that would prevent the further adoption of this method of insuring safe milk. In an industry so close to the public health it would be highly desirable to reach the point of attainment at which all tuberculous cattle were removed from the dairy herds. Since 1917 the federal government has been aiming at just that in its cooperation with the different states in testing, condemning and slaughtering tuberculous cattle. It is extremely interesting to note the changes in the death rate of tuberculosis in man that have occurred in that period. H. R. Smith of the National Live Stock Exchange calls attention to figures compiled from data from the U. S. Bureau of Animal Industry and the Bureau of the Census. The human death rate from respiratory tuberculosis in the United States in 1918 was 128.6 per hundred thousand of population, but it has decreased every year since then and last year was 56.6, or less than half what it was in 1918. The number of cattle tuberculin tested under this program in the year ended June 30, 1932, was nearly thirteen and a half million.

In this huge number, 1.9 per cent had a positive tuberculin test in contrast to 4.9 per cent in the cattle tested in 1918. As a matter of record, the aggregate number of cattle tested in all these years under this program has been 115,170,388, and among them 2,693,570 reactors were found. It cannot be claimed that the cooperative program of the government for the eradication of bovine tuberculosis alone has been responsible for the decline in the tuberculosis death rate, but it certainly is significant that during the eighteen years previous to 1918 the death rate of tuberculosis other than respiratory did not decline, in fact, the trend was slightly higher. This mortality rate in the United States in 1900 was 21.4 per hundred thousand of population. In 1917 it was 22.5 and through the intervening years it no time did it fall below the rate that prevailed in 1900. Various influences were at work from 1900 to 1917 to reduce the mortality rate of respiratory tuberculosis and they succeeded, but they did not reduce the mortality rate of other forms of tuberculosis. Since the government's campaign was instituted, however, the trend of the mortality rate of tuberculosis other than respiratory has been entirely different. The rate has been less for each succeeding year, and in 1932 it was 6.4. The removal of hundreds of thousands of tuberculous cattle from the herds that supply milk was coincidental with the great decline in the death rate from tuberculosis other than respiratory. It would seem to substantiate the work of investigators who found long ago that bovine tuberculosis was responsible for a great many cases of extrapulmonary tuberculosis in man.

ALBERT ABRAMS REDIVIVUS

In the department of THE JOURNAL devoted to reports by the Bureau of Investigation appears in this issue an account of an exceedingly impudent attempt to exploit anew the so-called electronic reactions of Abrams. One is inclined to remark that there are no new hokums, there are merely the old hokums introduced in a new way. Barnum knew that the will to believe is perennial, the technique of the magician need not vary, one merely diversifies the *materia magica*. The idea of special vibrations for different diseases can be found among the concepts of ancient centuries. But the engineer who would revive the Abrams doctrine has introduced new wrinkles, which must be the product of a training in engineering. The physician who scans the pictures of the Food and Remedy Test Set and the cow, so scientifically hitched, which the Bureau of Investigation provides for his delectation, will realize how a training in engineering can help a man who yearns for a medical career. The reason for this comment in association with the extraordinarily complete analysis by the Bureau of Investigation of the claims of Engineer F. C. Ellis lies in the concluding two paragraphs of the report. The Micro-Dynameter of Mr. Ellis has been exhibited at a meeting of the Inter-State Postgraduate Medical Assembly. A few of the physicians who derive their scientific pabulum through that organization have apparently invested in the device and thereafter been unable to find it of the scientific worthiness which at the time of investment it seemed to possess. Moreover, a

¹ Park W. H. and Krumwiede Charles. The Relative Importance of the Bovine and Human Types of Tubercle Bacilli in the Different Forms of Tuberculosis. J. M. Res. 27: 109. 1912-1913.

so-called medical periodical, *Clinical Medicine and Surgery*, has aided promotion of the device through its advertising columns, indeed, Mr. Ellis flaunts a letter from the editor of that publication, Dr. George B. Lake, in support of his contentions. It seemed when the late but not too greatly lamented Abrams passed from our midst—from pneumonia before he even hatched himself up to a machine—that his cult would pass soon from the scene. Usually these thaumaturgies disappear within a few years of the magician who promotes them. Little has been heard of Abramsism since that time and many a medical scrap heap yields the coils and wires that once were the heart and soul of the Abrams box. Yet now like a spirit from beyond the sepulcher emerges the Micro-Dynameter of Mr. Ellis. And a medical organization and a medical periodical are available to help rap the tables and shake the tambourines to assist the materialization. The spirit of Barnum must be chuckling beyond the Styx, unless perhaps exhausted by its laughter when viewing the multitudes who visited the india rubber man and the stuffed whale at A Century of Progress Exposition.

CAPILLARY PERMEABILITY TO LIPIDS

Attention has recently been directed to the need for further investigation of the physiology of digestion and absorption.¹ These functions of the organism are preparatory to the actual metabolism of the foodstuffs which, once circulating in the blood stream, are still more or less distantly removed from the cells of the tissues. Although the manner of transport of sugar and amino-acids is fairly well established, the mode of passage of lipids through the capillary walls into the interstitial fluid has not been satisfactorily explained. Man and Peters² have recently reported studies designed to elucidate the permeability of the capillary walls to the lipids of the plasma. Serums of normal persons were analyzed for cholesterol, total fatty acids and phospholipids before and after the subjects stood absolutely still for half an hour. Under these conditions of increased hydrostatic pressure there ordinarily occurs a passage of protein-free fluid from the capillaries into the tissues. In the present experiments it was observed that the increased concentration of cholesterol paralleled that of serum protein, indicating that this lipid failed to pass out of the capillaries as did the protein. In most of the subjects studied, the same observation was made with the total fatty acids and phospholipids. On the other hand, analysis of ascitic, pericardial and pleural fluids indicated that the lipids and protein occurred there in proportional concentrations. It is plain that these observations, though important from certain points of view, yield no explanation of the manner in which lipids traverse the walls of the blood vessels. As the transport, storage and utilization of lipids involve the transfer of this group of substances into and out of the capillaries there is presented here, as recognized by the Yale investigators, still another problem in the biochemistry of fats.

Association News

MEDICAL BROADCAST FOR THE WEEK

Talk over Network of the National
Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 5 to 5:15 Eastern standard time (4 o'clock, central standard time). The subject for Monday, January 8, is "Looking 1934-ward." The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association. Subjects and speakers for subsequent broadcasts will be announced weekly in *THE JOURNAL*.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

January 9 Fever
January 11 Drinking Water at Public Schools

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

January 13 Lister and the Development of Surgery

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Polluted Clams—A group of clam diggers who had previously been dropped from the state "clam diggers list" was recently arrested for handling polluted clams. They were given a suspended sentence of thirty days. The state department of health states that the conviction is an important advance in the better control of a clean clam supply in the San Francisco Bay region. The control is getting more difficult because of the increasing consumption of clams and the depletion of supply in beds that are clean.

New State Mental Hospital—Ground was recently broken for the new state mental hospital near Camarillo, Ventura County. The site is about 4½ miles from the Pacific Ocean and includes 1,610 acres, 1,200 being arable. The institution will ultimately cost about \$7,000,000 and house 6,000 patients, although funds now available will provide facilities for only about 800 patients. The plans are designed for the ultimate capacity, twenty-two wards to be devoted to each group of 2,000 patients. These three divisions will each have its own feeding, industrial and hospitalization units, administration quarters and apartments for officers. Patients will be housed in a connected group of one and two story ward units enclosing a large central court and twelve smaller courts. Spanish and Italian architecture will prevail. It is hoped to have the institution ready for the reception of patients May 1.

Society News—Dr. Henry Douglas Eaton, Los Angeles, was elected president of the Southern California Medical Association, November 4. Drs. Leslie H. Redelings, San Diego, and Francis B. Settle, Long Beach, vice presidents, and Robert W. Langley, Los Angeles, secretary.—Dr. Rodney A. Yoell, San Francisco, addressed the San Joaquin County Medical Society in Stockton, November 2, on medical economics.—Dr. Henry Chesley Bush, Livermore, conducted a clinic on tuberculosis before the Sonoma County Medical Society, recently.—Dr. Hugh Cabot, Rochester, Minn., discussed "The Management of Bilateral Renal Calculi" before the Los Angeles Surgical Society, December 18. Dr. Allen B. Kanavel, Chicago, addressed the society, December 8, on problems in traumatic surgery of the hand.—Dr. Albert H. Rowe, Oakland, addressed the Fresno County Medical Society, recently, on "The Challenge of Allergy in Medical Practice"—Dr. Wil-

ham Boyd, professor of pathology, University of Manitoba Faculty of Medicine, gave the Colver lectures of the College of Medical Evangelists, December 18-19. His subjects were "Bacterial Infections of the Heart" and "Tumors of the Neck."

Popular Medical Lectures—The fifty-second course of popular medical lectures to be given by Stanford University School of Medicine will open January 12 and continue on alternate Friday evenings until March 23. The following speakers will participate:

Dr. Edmund W. Butler, January 12, Organization of Medical and Surgical Emergencies in San Francisco.
Dr. Ray Lyman Wilbur, January 26, Medicine in Community Service.
Agnes Fay Morgan, Ph.D., February 9, Relation of Diet to Health.
Mary C. Rixford, O.T., February 23, Occupational Therapy.
Dr. George S. Johnson, March 9, Role of Psychiatry in Preventive Medicine.
Joseph C. Hinsey, Ph.D., March 23, Contributions of Medical Science to Our Knowledge of Pain.

COLORADO

Physician Donates Athletic Field—About 3¼ acres of land was presented to the board of regents of the University of Colorado, November 14, to be used as an athletic field for students and members of the faculty. The property which adjoins the campus of the medical school and Colorado General Hospital, Denver, will be named in honor of the donor, Dr. Horace G. Wetherill, Monterey, Calif., who was professor of gynecology in the medical school for many years. Dr. Wetherill, who has retired from practice, was formerly president of the Denver County Medical Society, the Colorado State Medical Society and the Western Surgical Association.

CONNECTICUT

Break Up Narcotic Ring—An illicit traffic in narcotics in Connecticut is believed to have been broken up by the arrest, November 9, of seven leaders of two narcotic rings which have been dealing almost exclusively with the illegal transportation of diacetylmorphine (heroin). Drugs valued at nearly \$30,000 were confiscated by the agents. Narcotics were supplied to adjacent states.

Scholarship Awarded—Yale University School of Medicine, New Haven, has awarded the Perkins Scholarship to Miss Lena Halpern, third year student. The scholarship, founded in 1914 by the widow of George C. Perkins, is given annually to the student making the best record in scholarship in the basic subjects of the medical and biologic sciences. Miss Halpern led her class at Yale in this respect and she had the highest average grade in a group of 593 medical students from all sections of the country who took the National Board examinations, part one, last June. She obtained a bachelor's degree at Hunter College in 1926 and a master's degree from Columbia University in 1930.

GEORGIA

Mental Hygiene Clinic Discontinued—A free clinic for mental hygiene, conducted by the city-county health unit of Macon and Bibb County, was discontinued, December 1, as a part of an economy program instituted by the state board of control, newspapers reported. The clinic has been in operation for twelve years and was under the supervision of Dr. Young H. Yarbrough, Milledgeville.

ILLINOIS

Sanitation Program to Prevent Typhoid—With the objective of eliminating sources of typhoid, the state health department has announced a program of sanitation in the southern part of the state, where, in thirty-four counties, the prevalence of typhoid is twelve times higher than in the northern third. With only one seventh of the population, the southern third of Illinois has fully one half of the state's typhoid cases each year. Last year the sixty-eight counties of the state had fifty-eight deaths from the disease, while the thirty-four counties in the southern section accounted for sixty-nine. An engineer of the U. S. Public Health Service has been assigned to Illinois to assist the state department of health in planning, organizing and supervising the project.

Chicago

Sentenced for Holdup of Physician—Judge Epstein sentenced Stanley Kaszulowski to serve from one year to life in prison, December 5, after he had been found guilty by a jury of robbery with a gun. The victim was Dr. Edward H. Warszewski, a member of the Chicago Medical Society. Kaszulowski was a member of the bandit gang that specialized

in "fake calls" and the holdup of physicians. Three of his companions were sentenced to 100 years each in the penitentiary, August 14, after they pleaded guilty to the murder of Dr. Bernard F. Garritz.

Dr. Craig to Lecture on Amebic Dysentery—Dr. Charles F. Craig, director of the department of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans, will give the second Jessie Horton Koessler Lecture of the Institute of Medicine of Chicago, January 26. He will discuss amebic dysentery. Officers of the institute, named at the eighteenth annual meeting, December 13, are chairman of the board of governors, Dr. Ludvig Hektoen, president, Dr. Joseph L. Miller, vice president, Dr. Vernon C. David, secretary, Dr. George H. Coleman, and treasurer, Dr. John Favill.

Address by Dr. Copeland—Dr. Royal S. Copeland, senator from New York, will address the Chicago Medical Society, January 17, on the Copeland bill. Dr. Arthur J. Cramp, director, Bureau of Investigation, American Medical Association, Chicago, will discuss the bill. Dr. Everts A. Graham, Bixby, professor of surgery, Washington University School of Medicine, St. Louis, will participate in a symposium on the gallbladder in general practice before the society, January 24, discussing the surgical aspect. Drs. George H. Coleman and Anton J. Carlson will consider internal medicine and physiology, respectively.

INDIANA

Society News—Speakers before the Indianapolis Medical Society, December 19, were Drs. Millard H. Foster on "Sexual Theory of the Neuroses," Howard B. Mettel, "Role of Allergy as Applied to General Medicine," and Bert E. Ellis, "Obstruction of the Larynx." Dr. Henry S. Leonard was elected president of the society, December 5. At a meeting of the Gibson County Medical Society in Princeton, December 11, Drs. John L. Morris and Amos H. Rhodes, Princeton, spoke on pneumonia and eye infection including corneal ulcer, respectively. Drs. Everett E. Padgett, Indianapolis, and Samuel Kennedy, Shelbyville, discussed medical economics before the Henry County Medical Society in Lewisville, December 7. Dr. William J. Butler, Grand Rapids, addressed the Elkhart County Medical Society, December 7, on "Acute and Chronic Gonorrhea." The Noble County Medical Society was addressed in Kendallville, December 12, by Dr. Merlin H. Draper, Fort Wayne, on tuberculosis. Dr. Ernest O. Nay, Terre Haute, talked on "The Relief of Prostatic Obstruction by the Electroscope" before the Vigo County Medical Society, December 12.

KENTUCKY

Personal—Dr. Elijah H. Maggard, superintendent of Eastern State Hospital, Lexington, has been transferred to Central State Hospital, Lakeland, to succeed Dr. William A. Quinn. Dr. Edward Davenport succeeded Dr. Maggard. Dr. George L. Thompson, Calhoun, health officer of McLean County, was elected chairman of the Green River Valley Public Health Association at its annual meeting in Hartford, November 9. Dr. Theodore Sallee, Covington, has been appointed health officer of Covington to succeed Dr. James P. Riffe, who has been elected coroner of Kenton County.

Society News—The Physicians and Dentists' Bureau for credit information and collection of accounts has been formed in Ashland with the approval of the Boyd County Medical Association. A joint meeting of the Harlan County Medical Society, the Cumberland Valley Medical Society and the Southeastern Kentucky Dental Society was held in Harlan, December 6. Among other speakers were Elmer C. Hume, D.D.S., Louisville, on traumatic surgery of the facial structures and Dr. Addie M. Lyon, Frankfort, eugenic sterilization. Dr. Earnest R. Goodloe, Paducah, addressed the Greenup County Medical Society in November on intravenous medication. Dr. Leroy U. Gardner, Saranac Lake, N. Y., addressed the Jefferson County Medical Society, Louisville, December 4, on pathology of pulmonary tuberculosis.

MAINE

Survey of Malnourished Children—The Maine Medical Association is cooperating with the state department of health, the Maine Public Health Association and local agencies in a plan to investigate and report on malnutrition in children of the state. Since local conditions are a factor, the organization of the plan has been left to the county medical societies with recommendations that they confer with local health officials. Arrangements will be made with school authorities for the examinations.

Society News—At a meeting of the Portland Medical Club, November 7, Dr Henry W Lamb discussed "Joint Tuberculosis"—Dr Harry I Friedman Boston, conducted a clinic on cancer before the Oxford County Medical Association in Rumford, recently, and gave an address on the same subject—The Penobscot County Medical Society was addressed in Bangor November 21, by Dr Elliott C Cutler Boston on "Total Thyroidectomy in the Treatment of Heart Disease" and Dr Channing Frothingham Boston discussed uremia, both physicians also conducted clinics—At a meeting of the Piscataquis County Medical Society at Dover-Foxcroft November 23, Dr Adelbert B Allen, Waterville, discussed diseases of the prostate

MARYLAND

Dr Wilmer to Retire as Director of Ophthalmologic Institute—Dr William H Wilmer will retire as director of the Wilmer Institute of Ophthalmology at Johns Hopkins University School of Medicine, Baltimore, July 1, to comply with regulations providing that professors leave the faculty when they reach the age of 70. The Wilmer institute was inaugurated in 1925, following the completion of a \$3,000,000 fund, the income of one third of which serves for the maintenance of the department. The income of the second million is used for the support of beds in the clinic for persons unable to pay, and the third million is devoted largely to the construction and equipment of the necessary buildings for housing the department. Dr Wilmer has been director of the institute since its establishment, carrying a concurrent appointment as professor of ophthalmology. He served in a similar capacity at Georgetown University School of Medicine, Washington, D C, from 1906 to 1925. Dr Wilmer was born in Powhatan County Va, in 1863. He graduated in medicine at the University of Virginia in 1885, taking graduate study at the New York Polyclinic and various hospitals of Europe. In 1889 he established practice in Washington. D C. Georgetown University conferred the degree of doctor of laws on Dr Wilmer in 1919, and Princeton the degree of doctor of science in 1926. Now a brigadier general of the medical reserve corps, Dr Wilmer's service in the army was concluded in 1918 as a colonel. Until 1918, he was officer in charge of the army medical research laboratories, when he assumed a similar responsibility for the American Expeditionary Forces in France, for one year. He was awarded the Distinguished Service Medal in 1919. Dr Wilmer has held official positions with several scientific societies and contributed to the literature on ophthalmology and medical aviation. He plans to continue with his private practice and writing.

MASSACHUSETTS

Society News—Dr Donald Gregg, Wellesley, was named president of the Massachusetts Society for Mental Hygiene November 23, and Dr Charles E Thompson, Gardner, secretary. Speakers at the annual meeting of the society included Dr Lawrence K Lunt Concord, Payson Smith Ed D, Boston. Dr Henry B Elkind and Dr Clarence M Hincks, director National Committee for Mental Hygiene, New York.

In Honor of Dr Shattuck—The name of Van Dyke Street, which adjoins Harvard University Medical School, has been changed to Shattuck Street in memory of Dr Frederick C Shattuck. The street is a private thoroughfare and the change of name was made by authority of the Harvard Corporation and neighboring hospitals. Dr Shattuck graduated from Harvard College in 1868 and from the Harvard Medical School in 1873. He became associated with the teaching staff in 1879 and served as Jackson professor of clinical medicine from 1888 to 1912. Following his retirement, he was a member of the board of overseers from 1913 to 1919 and remained actively interested in the progress and development of the institution until his death in 1929.

MICHIGAN

State Society Night—January 15 has been designated 'State Society Night' by the Wayne County Medical Society, when the program will be presented by members of the council of the Michigan State Medical Society.

George L LeFevre Muskegon president State Society Objectives
Richard R Smith Grand Rapids president elect State Institutions
Burton R Corbus Grand Rapids chairman Council Responsibilities
Frederick C Warnshus Grand Rapids secretary The State Society
Its Activities Strength and Weakness

An opportunity will also be presented to members of the county medical society to ask questions. Following this meeting, a social hour will be held in honor of two past presidents

of the Wayne County Medical Society, Drs Frank A Kelly (1923-1924) and Henry A Luce (1925-1926).

Society News—The Detroit Obstetrical and Gynecological Society was addressed, December 5, by Drs Harold A Furlong, Pontiac, on "Repair of the Urethra Following Obstetrical Trauma" and Alexander M Campbell, Grand Rapids "Radio-que Media in Gynecological and Obstetrical Diagnosis"—The Bay County Medical Society was addressed, November 8, by Dr Henry K Ransom, Ann Arbor, on "Surgical Diseases of the Female Breast"—Dr Grover C Penberthy, Detroit, addressed the Gratiot-Isabella-Clare County Medical Society in Alma, November 9, on osteomyelitis in children—At a meeting of the West Side Medical Society, Detroit, December 7, proposed changes in medical practice were discussed by Mr William J Burns and Drs Henry A Luce and Edgar E Poos—A symposium on automobile injuries was presented before the Wayne County Medical Society, December 18, by Drs Elisha S Gurdjian, Alfred D LaFerte Harry W Plaggemeyer, Harold K Shawan and Claire L Straith and Inspector Henry J Garvin of the Detroit Police Department—Dr Myron William Chitt Flint, was elected president of the Michigan Association of Roentgenologists, November 24, succeeding Dr Augustus W Crane, Kalamazoo.

MINNESOTA

Society News—Speakers before the Hennepin County Medical Society, December 13, included Leroy S Palmer Ph D, of the University of Minnesota on "Clinical Nature of Vitamins and Their Distribution in Foods" and Drs Charles B Wright and Arthur A Wohlrabe, on diets in treatment of ulcerative colitis and gallbladder disease, respectively—Dr Charles H Mayo Rochester, has been reelected president of the Minnesota Public Health Association.

Tuberculosis Program in Hennepin County—To stimulate interest in the early diagnosis of tuberculosis, the Hennepin County Tuberculosis Association is furnishing to physicians of the county a tuberculin syringe and diluted old tuberculin in a sterile vial. This service includes delivery to the physicians in their offices of a fresh supply of diluted tuberculin once every two weeks. Complete instructions are also given for applying and reading the Mantoux test. The tuberculosis association plans to inaugurate an educational campaign for the public later, stressing the importance of the tuberculin test and the x-rays in early diagnosis.

MISSISSIPPI

Society News—The Central Medical Society was addressed in November, among others, by Drs M A Sanchez-Vigil Managua, Nicaragua, on "Practice of Medicine in Nicaragua," and Frank H Hagaman, Jackson, "Resection of Sympathetic Nerves for Relief of Pelvic Pain"—Dr Irvin W Barrett, Clarksdale, among others, addressed the Clarksdale and Six Counties Medical Society, November 8 on hay fever, and Dr William H Brandon Clarksdale, sterility—Speakers before the East Mississippi Medical Society, October 19, were Drs Leonard Hart, Meridian, and James S Speed Memphis Tenn, heart disorders and fractures of the elbow joint, respectively—Dr James B McElroy, Memphis, Tenn, discussed the treatment of malaria, among other speakers, before the North Mississippi Medical Society in Oxford, October 25.

NEW JERSEY

Princeton Investigates the State Health Department—In a recent investigation of the state government conducted by Princeton University at the direction of Governor Moore, a number of recommendations were made concerning the state health department. To increase the revenue of the department the survey suggested that charges be made for examinations to test qualifications of persons desiring employment in fields closely connected with public health and for licenses issued to establishments handling foodstuffs. It was recommended that bakeries, canneries and confectioneries be added to the list of such establishments, removing these from the jurisdiction of the department of labor. Other license fees suggested were from individual milk plants from which milk is imported into New Jersey. Regulation of health conditions among persons who work at home for factories was urged as a function of the health department rather than the department of labor, the cost of which would be distributed among the contractors distributing such work. Among internal changes recommended were restoration of the publication of *Public Health News*, the department's bulletin, combination of the bureau of venereal

disease with the bureau of local health administration which handles problems concerned with other communicable diseases restoration of appropriations to provide offices and help for district health officers, and abolishment of the health officer of the port of Perth Amboy

NEW YORK

Society News—The ninth annual meeting of the New York State Committee of the American Society for the Control of Cancer was held in Rochester, December 12. A clinical conference was held in the morning at Strong Memorial Hospital, Rochester, and in the evening Dr. Burton T. Simpson, chairman of the state committee, addressed a public meeting at the Charlotte High School. The Buffalo Surgical Society for its December meeting visited clinics conducted by Dr. Donald Guthrie at Sayre, Pa.

New York City

Guest Lecturers at Medical School—The Clinical Society of the New York Polyclinic Medical School and Hospital is presenting a series of guest speakers the first Monday night in each month. Dr. Ralph Pemberton, Philadelphia, spoke, November 6, on "Newer Developments in Arthritis," and Drs. Elliott P. Joslin, Boston, and Francis M. Pottenger, Monrovia, Calif., December 4, on "Diabetic Gangrene—The Chief Menace to the Diabetic Today" and "Conservative Versus Operative Measures in the Treatment of Pulmonary Tuberculosis," respectively. Speakers to come in the series are:

Dr. Frank H. Lahey, Boston, Esophageal Diverticulum: Its Diagnosis, Surgical Management and End Results, January 8.
Dr. Walter L. Biering, Des Moines, Iowa, President Elect, American Medical Association, Coronary Artery Disease, January 8.
Dr. Grant I. Ward, Baltimore, New Developments in Electrosurgery, February 5.
Dr. William D. Cutter, Chicago, The Educational Program of the American Medical Association, February 5.
Dr. John Shelton Horsley, Richmond, Va., Cancer of the Stomach, March 5.
Dr. Dean Lewis, Baltimore, President, American Medical Association, Surgical Diseases of the Breast, April 2.
Dr. George W. Crile, Cleveland, End Results of Denervation of the Adrenal Glands for Neurocirculatory Asthenia, Peptic Ulcer, Diabetes and Epilepsy, April 2.

Dr. Richard Kovacs is president of the clinical society and Dr. Thomas J. Tobin, secretary.

Course in Physical Therapy—Six lectures and demonstrations comprise the course in physical therapy to be opened by the Bronx County Medical Society, January 8, under the direction of Dr. Frederick E. Bruer. No fee will be charged. Following is the schedule:

January 8, External Heat Measures Including Hydrotherapy, Dr. Heinrich F. Wolf.
January 12, Medical Diathermy, Dr. Richard Kovacs.
January 15, Massage and Exercise, Dr. Wolf.
January 19, Low Frequency Currents and Electrodiagnosis, Dr. Kovacs.
January 22, Surgical Diathermy, Dr. William Bierman.
January 26, Ultraviolet Radiations, Dr. Bierman.

Dr. Rice Appointed Health Commissioner—Dr. John L. Rice, for several years health commissioner of New Haven, Conn., has been named health commissioner of New York, succeeding Dr. Shirley W. Wynne, retired. Dr. Rice, who is 46 years of age, was born in Connecticut. Following his graduation from Johns Hopkins University School of Medicine in 1917, Dr. Rice engaged in medical and sanitary work in Central America, Trinidad and Puerto Rico for the Rockefeller Foundation. On returning to the United States he was health officer of Mason County, Kentucky, and later held a similar position in Albany, N. Y. Dr. Rice is president of the Connecticut Public Health Association. He and Dr. George C. Ruhland, health officer of Syracuse, recently spent several weeks in Germany and Austria as members of a party of municipal executives from American cities, studying public health conditions and problems.

NORTH CAROLINA

University News—Dr. John Shelton Horsley, Richmond, conducted a clinic at Duke Hospital, Durham, December 2, on lesions of the stomach and colon, and Dr. Eldridge L. Eliason, Philadelphia, December 7, on fractures. Dr. Estelle Ford Warner of the U. S. Public Health Service lectured, December 13, on child hygiene and Dr. Charles W. Stiles, also of the service, December 8, on hookworm.

Society News—Dr. George Curtis Crump, Asheville, addressed the Buncombe County Medical Society, November 6, on diseases of the gallbladder. Dr. Joseph Colt Bloodgood, Baltimore, conducted clinics on cancer at Wake Forest College School of Medicine, December 1-2. Dr. Samuel B. McPheeters addressed the Mecklenburg County Medical Society, Charlotte, December 5, on latent and reinfection tuberculosis.

Dr. Roy R. Kracke, Atlanta, spoke, November 21, on "The Nutropic State."

Dr. MacNider Receives Medal—The Southern Medical Association at its annual session in Richmond in November awarded its annual gold medal for notable achievements in research to Dr. William deBerniere MacNider, Kenan research professor of pharmacology, University of North Carolina School of Medicine. Dr. MacNider is a native of North Carolina, received his education in the state university, and has been a member of the faculty since 1905. He was president of the Medical Society of North Carolina, 1925-1926, chairman of the section on pharmacology and therapeutics of the American Medical Association 1926-1927 and is at present president of the American Society for Pharmacology and Therapeutics. Since 1930 he has been a member of the National Board of Medical Examiners.

OHIO

Past Presidents' Dinner—The second annual banquet of the Past Presidents' Association of the Summit County Medical Society was held in Akron, November 22. The three oldest members of the group of about twenty-five, Drs. John Henry Seiler, Dell S. Bowman and Samuel St. John Wright, were elected honorary presidents and Dr. Joseph N. Weller, president. Dr. Seiler, the oldest member, was president of the society in 1898 and in 1903. Following the dinner the remainder of the society was invited to hear an address by Dr. George E. Follansbee, Cleveland, chairman of the Judicial Council of the American Medical Association, on "The Practice of Medicine—Profession or Trade."

Society News—Dr. Wade W. Oliver, professor of bacteriology, Long Island College of Medicine, Brooklyn, gave an address on science and art entitled "Continuity," before the Cincinnati Academy of Medicine, December 18. Dr. Donald G. Ralston, McConnellsville, addressed the Ashland County Medical Society, November 29, on childhood tuberculosis. Dr. Berton M. Hogle, Troy, addressed the Miami County Medical Society, Piqua, November 8, on anesthesia. Dr. Herbert M. Platter, Columbus, addressed a joint meeting of the Marion Academy of Medicine and the Marion County Bar Association, November 14, on "Medicolegal Relationships." Dr. Jonathan Forman, Columbus, addressed the Huron County Medical Association, Willard, November 15, on allergic diseases.

OKLAHOMA

Society News—Harper County physicians and dentists have formed a society to be known as the Harper County Medical and Dental Society, with Dr. Hardin Walker, Rosston, as president. Dr. Charles P. Bondurant, Oklahoma City, addressed the Pontotoc County Medical Society, recently, on skin disease.

PENNSYLVANIA

Dr. Reed Wins Academy Prize—Dr. Josiah F. Reed was awarded the Seibert Memorial Prize of the Harrisburg Academy of Medicine at the annual banquet, November 22. The award, which is \$500, to be used in visiting medical centers of Europe, was established in memory of the late Dr. William Seibert, Steelton, by his sister, the late Anna Mary Seibert. It is given every two years to a member of the academy who has done notable work. Dr. Reed is an obstetrician on the staff of the Harrisburg Hospital.

Meeting on Medical Economics—The Allegheny County Medical Society devoted its entire meeting, December 19, to discussions of emergency health and welfare problems. Speakers were Drs. Harold A. Miller, director, state emergency relief board; Walter F. Donaldson, secretary, Medical Society of the State of Pennsylvania; Benjamin Franklin Royer, vice chairman, state emergency child health committee; Charles H. Smith, Uniontown; Robert A. Knox, Washington; and Henry T. Price, Pittsburgh, chairmen of emergency child health committees in Fayette, Washington and Allegheny counties, respectively, and Alexander H. Colwell, Pittsburgh.

Philadelphia

Society News—Dr. Arturo Castiglioni, professor of the history of medicine in the University of Padua, delivered the Nathan Lewis Hatfield Lecture of the College of Physicians of Philadelphia, November 29, on "The Medical School at Padua and the Renaissance of Medicine." Dr. George Dorance delivered an oration before the Philadelphia Academy of Surgery, December 4, on "Ligation of the Great Arteries of the Neck." Drs. Alexander Randall and Edward Campbell presented a paper on "Value of Nephrolysis, Ureterolysis and

Nephropexy in Selected Cases" — Dr Frederick M Law, New York addressed the Philadelphia Laryngological Society, December 5 on "Errors in Interpretation of X-Rays of the Mastoids and Sinuses" — Speakers at the meeting of the Obstetrical Society of Philadelphia, December 7 were Drs Ross B Wilson on "Transverse Positions of Vertex Presentations", Edward A Schumann and William E Parke "Endometriosis of the Abdominal Wall," and Lewis C Scheffey, "Infrequent Complications of Uterine Cancer with Certain Clinical Observations"

Joseph W England Dies — Joseph Winters England, an Associate Fellow of the American Medical Association, died of a sudden heart attack, December 2, aged 70. Mr England was graduated from Philadelphia College of Pharmacy and Science in 1883. In 1902 he became consulting pharmacist to the Smith, Kline and French Laboratories, remaining in that capacity until his death. He took an active part in pharmaceutical organization activities having served as president of the Pennsylvania Pharmaceutical Association in 1926 and of the Philadelphia branch of the American Pharmaceutical Association in 1921. For many years he was secretary of the publication committee of the *American Journal of Pharmacy* and chairman of the committee on publication of the American Pharmaceutical Association. In 1910 he was a member of the Committee on Revision of the Pharmacopoeia. He was also active in the affairs of his alma mater, having been secretary of the alumni association from 1904 until his death and for the nine years 1924-1933 chairman of its board of trustees. In 1903 he received the honorary degree of master in pharmacy, honoris causa, from the college. He carried on extensive research and contributed many articles to the literature.

RHODE ISLAND

Superintendent Retires — Dr John M Peters has resigned after forty-four years as superintendent of Rhode Island Hospital, Providence. Dr Peters came to the hospital as an intern after his graduation from Harvard University Medical School in 1887 and two years later was appointed superintendent. At that time the hospital had 130 beds, in comparison with the present 600, and served 902 patients in a year compared with more than 10,000 last year. Dr Peters announced his resignation, November 3, his seventieth birthday, to take effect January 1. Dr William O Rice, assistant superintendent since 1909 has been named acting superintendent. Dr Peters was president of the American Hospital Association in 1909.

TEXAS

Society News — Physicians of Hardin and Tyler counties recently organized the Hardin-Tyler Counties Medical Society, with Dr James H Dameron, Silsbee, as president, and Dr John F Shivers, Woodville, as secretary. — Drs Samuel M Hill, Dallas, and Edward H Schwab Galveston, addressed the Dallas County Medical Society, November 9, on suprarenal insufficiency and hypertension, respectively. — Drs Robert M Barton and Robert F Short, Jr, Dallas addressed the Henderson County Medical Society, Athens, November 6, on "Cardiac Edema and Its Treatment" and "Surgical Treatment of Empyema in Children," respectively. — A medical society representing Lamb, Bailey, Hockley and Cochran counties was organized at a meeting at Littlefield November 21, with Dr I J Sparks, Olton, as president and Dr John G Little, Littlefield, secretary. A petition for a charter was sent to the Texas State Medical Association. — The Limestone County Medical Society was reorganized at a meeting in Mexia, November 14. Dr Joseph F Moore Coolidge, is president, and Oscar T Christoffer, Mexia, secretary.

VERMONT

Society News — Drs Thomas E Hays and Arthur Bradley Soule, Jr, Burlington, addressed the Franklin County Medical Society, St Albans, November 1 on arthritis. — Dr Ralph E Powell, Montreal Quebec, addressed the Northeastern Medical Society at Newport, November 10, on genito urinary infections. — The Rutland Clinical Club began a series of eleven meetings, November 14, with Dr John F Burgess, Montreal Quebec, as the first speaker, on diseases of the skin and their management.

WASHINGTON

Personal — Dr William M Beach, Shelton, has been appointed health officer of Mason County. Dr Donald E McGilivray, Port Angeles, of Clallam County to succeed the

late Dr Walter J Taylor, and Dr Allen Bonebrake of Klickitat County.

Hospital News — A new administration building and a receiving hospital for male patients are under construction at Western State Hospital, Fort Steilacoom, at a total cost of about \$300,000. The administration building will replace the present main building.

WEST VIRGINIA

Society News — Dr Byrl R Kirklin, Rochester, Minn, addressed the Kanawha Medical Society, Charleston, November 13 on "Less Commonly Recognized Lesions of the Gastro-Intestinal Tract." — Dr Solomon L Cherry, Clarksburg, addressed the Harrison County Medical Society at its November meeting, on "Treatment of Common Diseases of the Heart." — Dr W T Morris, Covall, discussed the 'Automatic Nervous System' at the quarterly meeting of the Wyoming County Medical Society, November 2. — The Cabell County Medical Society met at the Veterans' Administration Facility, Huntington, November 9, Drs Harvey M McClure and Agha B Musa of the hospital staff presented a paper on thrombo-anginitis obliterans.

WISCONSIN

Appendicitis Increases — A recent study of appendicitis in Wisconsin shows that the death rate from this disease has increased from 11.6 per hundred thousand of population in 1911 to 18.2 in 1930, or an increase of 56 per cent. Analysis of the cases by groups revealed that the increases took place among children under 10 years of age and persons past 30, mounting with age with the exception of children under 5. Among the latter the increase was 64 per cent, for the 5 to 9 group 13 per cent. Delay in calling a physician or refusal to follow his advice was found to be responsible for fatalities in most cases.

Society News — John A Lapp LL.D, professor of sociology, Marquette University, addressed the Milwaukee County Medical Society, December 14, on "Medical Service in the Program of Social Welfare." — Drs John E Mulsow and Herbert G Schmidt addressed the Milwaukee Oto-Ophthalmic Medical Society, November 28, on "Roentgenological Study of the Hypopharynx and Trachea" and "Fracture of the Mastoid" respectively. — Drs Alfred W Adson and Henry W F Woltman Rochester, Minn addressed the Barron-Washburn-Sawyer-Burnett Counties Medical Society, Rice Lake, November 13, on "Brain and Spinal Cord Injuries." — At a meeting of the Grant County Medical Society, Lancaster November 2, speakers included Drs William A Mowry, Madison on allergic reactions, and Gunnar Gundersen La Crosse, on duodenal obstructions. — Drs Harold E Marsh and Arnold S Jackson Madison, addressed the Marinette-Florence Counties Medical Society, Marinette, November 9, on surgery in heart disease and acute conditions in the abdomen, respectively.

GENERAL

World Narcotics Quotas Issued — The amounts of narcotics that may be used in every country of the world during 1934 have been announced by the League of Nations under authority of the Narcotics Limitation Convention adopted in 1931 and ratified by the required number of countries early in 1933. The total is nearly 50 tons, valued at approximately \$15,000,000 wholesale. For the principal narcotics the amounts are roughly morphine 40 tons including 26 tons of codeine, 1½ of diacetylmorphine, 2¼ of ethylmorphine hydrochloride and 5½ of cocaine. The United States will have the largest quotas in the world, except for diacetylmorphine, which is not allowed to enter the country. The maximum amounts for the United States of the five most important narcotics are morphine, 9,865 Kg 336 Gm, diacetylmorphine none, codeine 6,044 Kg 505 Gm, ethylmorphine hydrochloride, 522 Kg 968 Gm, and cocaine 1,140 Kg 688 Gm. Germany, France, Russia and Japan receive the next largest amounts. The convention requires each country to submit each year by November 1 an estimate of the amount it expects to require for medicinal purposes during the next year and if these estimates appear excessive the league may make inquiries, though it has no power to change the estimates. If a country does not submit an estimate, the league has authority to decide its needs and to enforce its decision. Forty-five countries and eighty-three territories submitted estimates for 1934 and the league board fixed quotas for twenty-three countries and thirty-one territories. Among the latter were Russia, China, Mexico, Argentina and Brazil. Russia however later submitted estimates.

Dec. 9, 1933

Progress in Technic at the Radium Institute

The report of the Radium Institute for 1932 shows important improvements in the treatment of cancer of the cervix and cancer metastases in the neck. In treating cancer of the cervix, it has been possible by a new form of vaginal applicator to increase dosage while increasing filtration, so as to keep within the limits of tolerance. The vaginal applicators now in use are spherical or cylindric, with rounded ends, so as to distribute pressure more evenly on the vaginal mucosa. The spheres are made of vulcanite, are 17 mm in diameter, and are perforated by a canal 7 mm in diameter into which fits a platinum container with a wall thickness of 1.5 mm, secured by a vulcanite plug at each end. The container can be filled with any desired amount of radon which is contained in glass capillary tubes. The cylindric applicators are of balclite with a wall thickness of 5 mm and contain a platinum tube 22 cm long in which the radon tubes are placed. The activity of the vaginal applicators has been increased from 10 mg of radium to 15 millicuries of radon. For intra-uterine application a gum elastic sheath 8 cm long and 0.8 cm in diameter holds three radium tubes in tandem each containing 10 mg of radium element. The uterine applicator and three or four vaginal applicators are inserted under gas-oxygen anesthesia and left for forty-eight hours. This combined application is repeated after a week, but between the two a further vaginal application is made forty-eight hours after the first in the knee chest position. This technic gives a dose of 2,880 mg hours in the uterus (the same as before) but an increase in the vaginal dose from 5,040 mg hours to from 5,500 to 7,000, according to whether three or four vaginal applicators are used.

In treatment of cancer metastases in the neck, the new technic seems to hold out more promise of success for the difficult problem of glandular metastases in the neck in cancer of the tongue. The present method consists in using a small number of high content tubes at increased skin distance. With a distance of 4 cm it was found that large fixed glandular masses disappeared. So far the method has been confined to inoperable cases, but the results seem to justify extension. A Columbia paste collar 2 cm thick is made, and the radioactive tubes are mounted on blocks of balsa wood 2 cm thick. The tubes are 4.5 cm long and the filter is 2.5 mm of lead attached to the wood. Generally four tubes are used, being arranged as a square of from 64 to 144 sq cm. The upper tube is parallel to and at the level of the lower ramus of the mandible when the superior cervical glands are involved. The time of exposure has gradually been increased until it is now ten hours daily for twenty days. Each tube contains 50 millicuries of radon and is made up to its original content every morning. The dose given is 280 millicurie days. The reaction is severe, there is a destructive dermatitis over a wide area and the patient feels ill for two or three weeks. The time is too short for a final estimate of the method, but the results are better than any previously attained.

Lead in Canned Sardines

At the Society of Public Analysts Dr. L. H. Lempitt and a collaborator read a paper reporting that canned sardines had been found seriously contaminated with lead. An apparent connection existed between the amount of solder exposed in the can and the lead content of the sardines. But solder was not the only source of lead, for it had been found in sardines packed in cans in which no lead could be derived from the

container. It had been shown that sardines cooked on grills covered with so called tin containing appreciable quantities of lead were badly contaminated with the latter, whereas if pure tin was used the lead content of the sardines fell to a negligible figure. The metal of the grills was the chief source of contamination with lead. The lead content of sardines should not be substantially more than from 5 to 8 parts per million. Higher figures indicated avoidable contamination in the preparation of the sardines before canning.

Epidemic of Gastro-Enteritis Affects a Whole Town

The town of Kidderminster, with a population of 30,000, has been stricken with an epidemic of gastro-enteritis, which has swept through it like one of the ancient plagues. One big school has had to close down and many business and work shops have been working with only half their staffs. Children have been most severely affected. The cause is supposed to be some contamination of the water supply. Policemen have made a door to door tour and handed notices to all householders advising them to boil their water for at least ten minutes before using it. Notices to this effect are also displayed everywhere including the cinemas. It is supposed that the heavy rains following the recent drought has caused 'foreign water' to drift into the water supply and brought the contagion. A chlorination plant has been installed in the reservoir, which has led to continuous improvement in the quality of the water.

Reduction of Crush Fractures of the Spine

In 1930 Mr. R. Watson Jones of Liverpool called attention to a simple method of reducing crush fractures of the spine now so common a result of automobile accidents, which can be carried out by any one who knows the rudiments of plaster work. The kyphotic deformity produced is due to acute flexion at the site of injury. If the patient is placed prone, supported only by his arms at the side of his head and by the front of his thighs and legs, leaving the trunk entirely unsupported, body weight alone is sufficient to give perfect anatomic reduction. Mr. Jones recommends that reduction be performed by arranging two tables end to end, with a space between slightly greater than the length of the patient's trunk. The front table is raised on blocks or chairs, so that it is about 2 feet higher than the other. The patient is lifted face downward on to the lower table, and a double layer of stockinet pulled over the trunk and stitched over the shoulders and beneath the perineum. He is then assisted into such a position that he is gripping the edge of the higher table with his abducted arms, his head resting on a small pillow. The lower table supports his lower limbs as high as the upper part of the thighs but between the groin and the neck there is no support. In this position he is unable to prevent his spine from sagging into full hyperextension. A plaster jacket is applied at once. At the recent meeting of the British Medical Association Mr. W. S. Haughton of Dublin endorsed the advice of Mr. Jones that these patients should be transported face downward. If the patient is placed face downward on the stretcher with a roll of coat or blanket under the upper part of the chest and another under the pelvis the spine will sag into hyperextension and even reduction of the deformity may take place during transport. This method of transport is now taught to ambulance surgeons.

Hospitals to Be Compensated for the Treatment of Road Accidents

The great strain on the resources of hospitals due to the treatment of automobile accidents has been reported in previous letters. Thanks largely to Lord Moynihan this condition is to be remedied. According to the law drivers of automobiles must hold a policy of insurance against the cost of accidents. A clause has been added to the road traffic bill providing that

when any payment is made under policy of insurance or by the owner of the vehicle in respect of death or bodily injury arising out of the use of an automobile on a road, and the dead or injured person has received treatment from a hospital, the insurer or owner must pay to the hospital the reasonable expenses incurred in such treatment up to \$250 for each person treated as an inpatient and \$25 for each person treated as an outpatient. In calculating these expenses, money received by the hospital in payment of a specific charge is to be deducted, but not money received under any contributory scheme. The cost of treating patients is to be calculated as the average daily amount of cost for each inpatient and the maintenance of the hospital and staff. At present many hospitals situated near the great highways are occupied with automobile accidents to the exclusion of those cases for which they were originally intended. It is calculated that the voluntary hospitals of this country are out of pocket to the extent of \$750,000 a year at least for the treatment of automobile accidents. The clause was agreed to without a division in the house of lords.

Payment of Physicians for the Treatment of Road Accidents

Physicians who give emergency treatment in road accidents have a grievance similar to that of the hospitals. In the house of lords, Lord Moynihan moved the second reading of the road traffic (emergency treatment) bill. He said that only about one physician in twenty received either thanks or remuneration for the emergency treatment of road accidents. He originally suggested that a maximum fee of \$15 would meet the case, but it was pointed out that a maximum fee would probably become the standard fee, which would be excessive. After a discussion the committee decided that \$3 would be a fair charge. He suffered a good deal of criticism from physicians for agreeing to this decision. In a great many cases it would be too little, but it is better than nothing which was what the majority got now. This sum would be paid by the insurance companies as part of the "third party risk." In supporting the bill, Lord Dawson, a physician said that physicians worked hard and looked forward to a quiet Sunday, but that was the day of all others when they were likely to be called to road accidents. In many cases the cost of the dressings they had to supply was a substantial sum. For the government the earl of Plymouth objected that the bill would fasten a liability on a man in respect to an accident for which he might not be in the least responsible. He sympathized with the grievance of hospitals and physicians, but he doubted whether the bill provided the right remedy. The government could not accept it and if it reached the house of commons would not undertake to provide facilities for its passage. Lord Moynihan expressed disappointment and urged the house to give the bill a second reading, which it did.

The Recognition of Foreign Medical Qualifications

At the opening session of the general medical council the president, Sir Norman Walker explained the conditions under which physicians from foreign countries or other parts of the British Empire could be registered and so enjoy all the privileges of British physicians. If the council was satisfied that the qualifications furnished a sufficient guaranty of knowledge and skill for the efficient practice of medicine, surgery and midwifery, it might recognize such qualifications. It is lawful to practice in Great Britain without a qualification, but an unqualified person cannot hold any medical appointment, do panel work, sign a death certificate or sue for fees. Most of the British colonies and dominions control medical education and registration and the council has found it easy to estimate the standards of any dominion with a view to giving or withholding reciprocity.

The French Congress of Therapeutics

The *Congres français de thérapeutique*, a new creation, was founded by Professor Loeper, who served as its first president. The first session, held at the *Faculté de médecine*, was well attended by scientists from all countries of Europe. In his inaugural address, Professor Loeper brought out that modern research in physiology, biologic chemistry, pharmacodynamics, physical therapy, serotherapy and organotherapy had completely transformed the old type of therapeutics, which justified the creation of this congress. So many communications were offered that it was necessary to organize three sections (medicine, pharmacodynamics, physical therapy), each held in a separate hall. The medical section considered, first, parenteral treatment of gastroduodenal ulcer. Professor Devoto of Milan described the good results secured by the subcutaneous or intravenous injection of various substances, among which he prefers sodium benzoate. He did not give an interpretation of its mode of action although it is possible that it stimulates the secretion of hydrochloric acid. The cures effected in this manner are, however, not permanent. François Moutier discussed treatments by shock methods and by vaccinations, referring to vaccines prepared with the micro organisms of dental pyorrhea. Mr. Debray dealt with the organotherapy, particularly injections of pepsin. Professor Glaessner of Vienna spoke on the same subject and also on the use of insulin and parathyroid hormones. Professor Pribram of Berlin, Mr. Feissly of Lausanne, Guido Mann of Trieste, Mr. Hernandez of Madrid, Mr. Besse of Geneva, Mr. de Beco of Brussels, Mr. Dinkin of Berlin, Mr. Vihardell of Barcelona, Mr. Foyer of Amsterdam, Pavel and Florin of Bucharest, and numerous French specialists, presented their views, without forming the basis for any generally accepted opinion, for all the treatments proposed were presented as having been successful. Another question studied was the treatment of colibacillosis. Fournau and Bovet gave a complete survey of all urinary antiseptics. Professor Vincent, in collaboration with Mr. Pacquet, gave an exposition of his general treatment with his anticolibacillary serum, which is applicable in all manifestations of *Bacillus coli*, including cholecystitis and neuropathic disorders. Mr. Baruk emphasized the last point and discussed colibacillary psychoses, frequent cases of which follow pyelonephritis and the puerperium. Mr. Chevassu reported his experience with Vincent's serum in urinary surgery, during the previous nine years. He reserves it for serious cases of septicemia and pyelonephritis, and as preparation for operative interventions. Mr. Hauduroy spoke on the uses of vaccines, autovaccines and bacteriophages in colibacillosis. Numerous communications were then presented recommending widely different forms of treatment: acridine, neoarsphenamine, derivatives of phenyl salicylate, vaccine-therapy, mineral waters and opotherapy, in endocrinopathetic dysequilibrium. The congress was supplemented by a comprehensive exhibit of pharmaceutical specialties.

Congress of the Anatomic Society

The congress of the *Société d'anatomie* was presided over by Professor Roussy. Two topics were discussed comprehensively. The first topic concerned the mechanism of cerebral hemorrhages. Prof. H. T. Deelman of Groningen took up the theory of Rosenblatt, which denies that cerebral hemorrhage has but one cause, as commonly believed, namely, rupture of a blood vessel. Rosenblatt contends that there are small hemorrhagic foci produced in advance by an alteration of the cerebral substance itself. Deelman thinks that such foci are only secondary and that one can provoke a cerebral hemorrhage by a partial obstruction of the arterial circulation. Prof. P.

Schwartz of Frankfort-on-Main thinks that there are three types of cases (1) lesions following vascular obliterations due to emboli, (2) lesions following obliterations due to arteriosclerosis, and (3) lesions without vascular obliterations or apoplexy due to hypertension. Jean Lhermitte submitted a comprehensive paper on the subject. He pointed out that Charcot and Bonchard's theory of multiple aneurysms is no longer tenable. Cerebral hemorrhage is a complex phenomenon, made possible by the fragility of the cerebral parenchyma, and is precipitated by a sudden stoppage in the arterial system. An anatomic study on the innervation of the visceral pedicles was the subject of papers by Professor Delmas of Montpellier and by Professor Kiss of Szegedin, who reached the conclusion that the structure of these pedicles is identical in the whole organism. Their fibers and cells are of the sympathetic type but combined with somatosensory fibers. There is therefore no reason to assume the existence, in the autonomic pedicles, of two categories corresponding to the orthosympathetic and the parasympathetic.

French Congress of Orthopedics

At the French Congress of Orthopedics, presided over by Professor Mathieu, Dr. Mutel of Nancy presented a paper on "Open Methods for the Reduction of Luxation of the Hip." Such methods are suited to only 8 per cent of the cases in children, and in adults only to the cases in which other methods have not given good results. This type of surgery often leads to ankylosis and should be rejected in bilateral luxations. One can base some hopes on the results of resection of the bone which adapts the length of the femur to the shortened muscle but imposes a permanent limp. The lively discussion that followed showed that, in France at least, the open method has few advocates. Even Mr. Mathieu opposed it, pointing out that it produces stiffness in the simple cases, that it is a grave intervention in difficult cases, and that, in fact, the technique is not yet well worked out.

Another paper, presented by Dr. Richard of Paris, dealt with chronic arthritis of the spinal column, a problem that is imperfectly understood and in which no diagnostic precision can be reached without radiography. He described the numerous types and also the disorders that may simulate it. The treatment varies, requiring in some cases immobilization (tuberculous arthritis) and in some cases progressive mobilization, after disappearance of the muscular contracture through rest, and requiring the use of radiotherapy and thermal treatments. Further communications were presented by Mathieu, Ombredanne, Roederer, Frolich, Graves, Mauclore, Rocher, Ponzet, Meyer, Guerin and Delrhaye. The congress next year will consider "Le thorax en entonnoir" (chief speaker, Mr. Garnier), and "Treatment of Spasmodic Paralysis, the Little Syndrome, and Encephalopathies" (chief speakers, Roudil of Paris and Delchef of Brussels). In 1935 the congress will consider "The Pathogenesis and the Treatment of the Vollmann Syndrome."

The French Assembly of General Medicine

The October session of the French Assembly of General Medicine was devoted to a study of syphilis in France. The chief speaker, Mr. Godlewski, stated that, during the five years that followed the war, there was a considerable increase in the cases of syphilis, then a rapid decline between 1925 and 1929. The situation at present is stationary, but there is a marked contrast between the frequency of syphilis in the rural districts and in the cities, the latter constituting veritable reservoirs of virus. There is no great difference in the relative distribution among the various social classes, but the situation is much better than formerly in the army and in the navy, in which prophylactic measures are vigorously employed. Syphilis too often remains unrecognized until the appearance of the tertiary

stage. Tubercles have become less grave, and one sees nowadays few severe cases of ataxia such as were formerly observed. Visceral localizations, especially aortic, are still frequent. It is generally noted that modern treatment of syphilis has greatly diminished its gravity. Recent cases of syphilis are more quickly suppressed than formerly, but so-called abortive treatment has not proved its efficacy and may give a false sense of security. The Wassermann test is still needed, but the negative results should be interpreted in a critical spirit. Chastity is the origin of syphilis in two thirds of the cases, in both the rural districts and the cities. Medically supervised prostitution is, to be sure, immoral, but it decreases the danger of infection. The antivenereal dispensaries have not given as good results as were expected, for patients, fearful of publicity, hesitate to visit them, often preferring to consult a practitioner who is not a specialist rather than the family physician. During the discussion, the extension of prophylaxis through the teaching of youth the dangers of venereal disease was unanimously approved. The exceedingly difficult differentiation of syphilitic aortitis and atheroma of old age was discussed at length. The present treatment of syphilis is still the subject of much controversy. An interesting graph prepared by Mr. Rimc enabled the assembly to note the relative quantities of the various drugs employed since 1920. It was clearly seen that trivalent arsenic is less used than formerly. Bismuth, particularly the hiposoluble forms, and mercury are being more widely used. Pentavalent arsenic has not sensibly varied since its appearance.

Resignation of Robert Davis

Robert Davis has resigned as superintendent of the American Hospital at Neuilly, which post he had accepted only for a period of eighteen months, by reason of other duties as head of the American Library in Paris. Dr. MacIlroy, director of the school of medicine of Richmond College, has been summoned as his successor.

BERLIN

(From Our Regular Correspondent)

Nov. 20, 1933

The Congress of Gynecology

The congresses held this year have not been so numerous as usual, but the Deutsche Gesellschaft für Gynäkologie held its regular congress in October, under the chairmanship of Stoeckel. The first topic on the program concerned gynecologic hemorrhages. Schroder of Kiel dealt chiefly with anomalies of menstruation. Instead of the usual terms menorrhagia, oligomenorrhoea, polymenorrhoea and metropathia, Schroder proposes a less ambiguous terminology. He divides the anomalies of menstruation into five classes: (1) increased and excessive menses, (2) too frequent or too rare menses, (3) supplementary hemorrhages, (4) hemorrhages not recognizable as menstrual discharges and (5) hemorrhages during the menopause. He emphasized the importance of the constitution with reference to these disturbances. Changes in the menstrual cycle often result from marked external influences, for example, after severe accidents. The importance of psychic influences affecting the menstrual cycle, while no doubt such exist, must not be exaggerated. Runge of Greifswald, in discussing treatment, warned against the uncritical use of organotherapeutic preparations. In the treatment of amenorrhoea, the onset of menstruation following the administration of certain preparations is not conclusive proof of their efficacy. The treatment of recurrent, climacteric metropathia haemorrhagica is relatively, firmly established. The preferred therapy is the equivalent of castration but effected by roentgen irradiation. When occurring in young women, the problem is vastly more difficult as the objective is to restore to normal functioning an ovary that is evidently functioning in

an inadequate and possibly also in abnormal manner. Opinions as to the value of radium irradiations were widely divergent. Whereas one group rejected them entirely, others emphasized that mild radium irradiation had often been found to have life-saving value in hemorrhages occurring in juveniles. In young women, the corpus luteum hormone is often likewise effective.

OPERATIONS BASED ON EUGENIC INDICATIONS

In discussing the second topic "Operations Based on Eugenic Indications," the speakers expressed absolute approval of the new law pertaining to sterilization (*THE JOURNAL*, Sept 9, 1933, p 866). Professor Kohlrausch of Berlin, a specialist in criminal law, called attention to the fact that hitherto the law did not justify an interruption of pregnancy based on eugenic indications. Bumke, psychiatrist of Munich, pointed out that mental disease had shown an increase in recent years. The indications for the interruption of pregnancy in mental patients depend on the degree of probability that the offspring will be abnormal, which can be assumed only in case both parents are mentally ill. The hereditary influence transmitted by weak-minded persons is not yet fully established, but if both parents are weak-minded the assumption is that 70 per cent of the offspring will be weak-minded, if only one parent is weak-minded the assumption is that about 50 per cent of the offspring will be weak-minded. In schizophrenia, with which 70 per cent of the mental patients in institutions are affected, a child has 50 per cent of a likelihood of becoming mentally ill if both parents are affected and 7 per cent of a likelihood if only one parent is schizophrenic. In weak-mindedness and in schizophrenia, the factor of education plays a large part in the decision, for often such parents are susceptible of being educated. Schizoid subjects should not be sterilized. The decision is difficult in epilepsy, for, while true epilepsy may be transmitted to offspring, the tendency cannot be said to be dominant, hence the decision must be based on the circumstances surrounding the individual case. If the symptoms of manic-depressive subjects are mild, sterilization should not be considered, but it becomes a question if the depressions are severe. The sterilization of alcohol addicts if the condition is severe, is much to be desired, for alcohol addicts are most unsuitable as fathers of families.

During the general discussion, physicians with Catholic antecedents pointed out that the sterilization law must be considered not only biologically but also metaphysically and ethically, with a borderline area between medicine and moral theology. The Catholic view compels the rejection of this law on ethical grounds, as it cannot assume the responsibility of separating sexual union from the propagation of new life.

CANCER OF THE CERVIX

The third main topic considered the early diagnosis and treatment of cancer of the cervix uteri. Hinselmann of Altona discussed the value of frequent colposcopy. Every leukoplakia should be regarded as a warning and it can always be discovered with the colposcope. An erosion demands no less attention. Von Mikulicz and Radecki (Königsberg) spoke on the radical operation, and Eymér (Heidelberg) on radiation therapy. These papers revealed that operation and irradiation are still contending for the supremacy. An important outcome of the whole discussion was the draft of a law, which the Deutsche Gesellschaft für Gynäkologie submitted to the federal ministry of the interior. In this bill the proposal is made to restrict absolutely the treatment of cancer patients to licensed physicians. The suggestion is made, too, that the insurance carriers (namely, the Krankenkassen) be required to subject annually every woman more than 30 years of age to an examination for cancer. The fourth topic on the program was "New Results of Research on Twins," which was presented by Verschuer of Berlin. The next session of the congress will be held in Munich, in October, 1935.

ITALY

(From Our Regular Correspondent)

Oct 15 1933

Discussion of Immunity at the "Volta" Convention

Each year there is held in Rome a convention organized by the Fondazione Alessandro Volta (associated with the Royal Academy of Italy), which is attended by some of the most eminent scientists in the world. The chief event of this meeting is the consideration of a single precisely drawn scientific topic, which reflects the progress of a scientific activity rather than its history and constitutes an attempt to unify the theories and the results of recent experiments. The topic chosen this year was "Immunity and Immunology." The convention was presided over by De Blasi, professor of hygiene at the University of Naples and the principal nations of Europe and America were represented. The delegates from the United States were Landsteiner, Flexner and Kahn, from England Nuttall, Topley, Muir and Wright, from France (among others), d Herelle and Besredka.

SEROLYSIN

The first meeting was presided over by Professor Landsteiner, Nobel laureate and member of the Rockefeller Institute in New York. Professor Petterson of Stockholm presented a paper on "Beta-Serolysin" which is a bactericidal substance in the blood serum different from the Buchner lysin, from which it may be distinguished by the fact that it is more resistant toward the influences that tend to block the bactericidal action of the serum. It is found in part in the precipitate euglobulin, and its bactericidal potency may be demonstrated in solutions of globulin. Certain micro-organisms under the action of the lysin do not provoke any formation of bacteriolytic immune bodies. If in the immunized animal an increase of bactericidal potency is observed, it should be attributed to other influences than the leukocytes. It is impossible to increase the specific bactericidal capacity when it is a question of acting on bacteria on which the cells of the organism itself do not exert a destructive action. As an example of a practical application of this fact, against anthrax and local staphylococcal infections active immunization by means of killed staphylococci is indicated. Professor Maragliano of Genoa affirmed that in tuberculosis any immunity present does not appear to be essentially an antibacterial immunity. The micro-organisms undergo various changes but are not destroyed and remain, for the most part, living and enclosed in old foci. Experiments show that, while it is easy to modify the germs coming from without, it is difficult to act on those already present in the body. The early infiltrate, which is regarded as the result of an exogenic reinfection, is, on the contrary, the rekindling of foci apparently extinguished but still certainly having an active influence.

Professor Rondoni agreed that immunity against tuberculosis is essentially histogenic, fibrogenic and encapsulative. His search for bacteriolysins proved negative. In 1915 and 1916 he studied the histologic reactions in tuberculous reinfection, demonstrating an early hematogenic reaction or polymorphonuclear mobilization in reinfected animals subjected to vital staining.

Professor Weichardt pointed out that one must distinguish between protective substances already present physiologically and substances obtained by means of immunizing processes. These various processes endeavor to eliminate the infection and, when their influence is not sufficient, the antibodies intervene.

IMMUNOCHEMICAL SPECIFICITY

The topic discussed by Karl Landsteiner of New York was "Immunochemical Specificity." He dealt with complex antigens obtained by means of combinations of various chemicals with protein substances and with the natural complex antigens. He described recent researches on peptides and the marked individual differences that are brought out experimentally in animals.

of the same species. In discussing the paper, Professor Abderhalden said that by experiments on defensive ferments it was possible to differentiate between strictly specific antigenic substances. The studies of the speaker are a bridge so to speak, between physiology and immunity for the solution of the problem of the composition of proteins, which it seems impossible to solve by chemical means. Professor Doerr of the University of Basel surveyed experiments carried out by his school on the antigenic action of arsenical compounds and searching then for arsenic in the antiserums secured. It was found that the latter do not contain arsenic and hence cannot be derived from the former; it is impossible therefore to synthesize antigens artificially.

In his paper on *The Bacteriophage in Its Relations to Immunity*, Prof. Felix d'Herelle presented evidence to show that every man and every animal has in the intestine a bacteriophage that lives in symbiosis. Its activity is not specific but it has a variable potency. If it is very potent the bacterium succumbs, if it is less potent the micro organism may resist it and acquire immunity to it, and then the bacteriophage is destroyed or accommodates itself to a bacteriophage symbiosis. Recovery from infectious diseases does not result from an immunizing process but from the bacteriophage and from the reactions that it provokes. The speaker demonstrated interesting therapeutic applications with bacteriophage in the prophylaxis and treatment of infectious diseases. A lively discussion followed the presentation of Professor d'Herelle. Professor Bertarelli of the University of Pavia asked questions about the thermostability of the bacteriophage and as to whether it was possible to set up a standard method to determine its presence. Professor Besredka of the Pasteur Institute in Paris asked the speaker how a bacteriophage injected intravenously can act when a small quantity of blood serum is capable of inhibiting its action. Professor Degkwitz of the University of Hamburg remarked on the composition and physical properties of the bacteriophage, which he regards as a ferment. In response to all questions, Professor d'Herelle reaffirmed that the bacteriophage is living matter and that its curative action is unquestionable. The process of recovery is through contact by the same route as the causal disease, as has been observed in various epidemics.

THE THEORY OF ANAPHYLAXIS

Professor Doerr of the University of Basel presented the official paper on the theory of anaphylaxis. He pointed out that the resemblance that some have endeavored to establish between the histamine reaction and the anaphylactic reaction is not tenable. There are substantial differences between the two reactions, for example in the period of latency and in the fact that, whereas repeated stimuli applied in the same concentration are always equally effective in anaphylactic experiments, on the contrary, it is necessary to increase considerably the dose of antigen, in order to secure a later muscular contraction. His experiments on anaphylactic heredity have forced him to assume the existence of a latent form of antibodies. The discovery of passive anaphylaxis and the reversibility of these experiments show that there does not exist an increased or a pathologically changed reactive capacity of the cells but only a normal susceptibility to the reactions of antibodies.

Professor Zironi, director, Institute of Microbiology, University of Milan, who spoke on *allergy in infectious diseases*, pointed out that not all allergic phenomena can be regarded as manifestations of hypersensitivity, in the strict sense of the word since many cases are due chiefly to a conflict of antigens with antibodies, independently of the sensitivity or reactivity of the cells. With regard to the causes of the hyperactivity, Professor Zironi said that the research on the subject is far from complete and that it would be necessary to study the period of incubation

of the infections, the problem of the virulence of the organisms, the genesis of the predisposition to the infections, and the course of many diseases. In the general discussion, Professor Frugoni of Rome described research carried out by his pupils, on the basis of which it has been discovered that in typhoid and in sepsis lenta due to *Streptococcus viridans*, the increase of antibodies in the circulation coincides with the disappearance of the bactericidal potency of the blood.

Professor Canonici of the University of Naples described his research and the research of Professor De Cristina on the phenomenon of sensitization and desensitization, affirming that recovery from infections occurs through the spontaneous development of desensitization of the patient, a process that can be provoked also by introducing into the organism, preferably by vein, small quantities of proteins of the micro organisms causing the disease.

The Lombard Medical Society

At a meeting of the Lombard Medical Society held in Milan Silvestro spoke on the hemoglobin in pulmonary tuberculosis. He pointed out that tuberculous anemias are due to toxic hemolysis rather than to defective regeneration of red corpuscles. Therapeutic pneumothorax and phrenic exeresis reduce the hemolysis with improvement in the anemia.

Arrighi and Corsari reported their observations in a number of cases of hemolytic splenomegalic icterus. They admit the possibility that a primary fragility of the blood cells and a primary hyperactivity of the reticulo endothelial system are essential factors underlying the hemolysis. Anatomic research reveals that in hemolytic icterus, the hyperplasia of the reticulo endothelial system although varying in degree in various cases, is usually of a uniform character namely splenohepatic, lymphoglandular or medullary. The organ most commonly attacked is the spleen. Splenectomy is always of great benefit in the treatment of the pure types of hemolytic icterus. It is particularly indicated in cases in which in addition to the characteristic hematologic and clinical manifestations of the disease, there are signs of other constitutional anomalies. The speakers regard biopsy of the liver for diagnostic and prognostic purposes, as useful and advisable to be applied in connection with any operative intervention performed on patients who present a splenopathy.

Chiovenda described twelve cases of glioma of the brain in which diagnosis of cerebral hemorrhage or softening of the brain (seven cases), encephalitis (three cases) and meningitis (two cases) were made. In the cases observed by the speaker there were no connections between regressive phenomena, course localization and the histologic type of the glioma.

Prophylactic Vaccinations

Professor Madsen of Copenhagen, chairman of the Health Committee of the League of Nations has published an article on vaccination applied during an epidemic to prevent an increase of the susceptibility to the infection, namely the so called negative phase. The report of the International Committee on Standardization shows that in the field of vaccination the fears are entirely unfounded. On the basis of his research, Madsen interpreted the rapid decline of the antitoxic potency of the serum to the neutralization or the fixation of a part of the antitoxin injected into the circulation. He explained that the later increase of antitoxin may be due to its formation or to its release from the organs or to a partial intravascular dissociation of the total antitoxic antigen formed originally. On the interesting problem of the negative phase questions were asked by Professor Ramon of the Institut Pasteur de Paris, Professor Doerr, Professor Kolle and others.

Prof. Lecomte De Nouy called attention to two phenomena that characterize immunity: the diminution of the absolute

potency of the static surface tension of the serum solution in the animal immunized or sensitized and the absolute increase of viscosity of the blood serum following the addition of antigens. He affirmed that the organism preserves the record of the reaction in the form of immunity. Although the serum has regained its normal behavior, it has been markedly changed with regard to viscosity and to its physicochemical equilibrium.

Professor Sachs of Heidelberg surveyed and criticized the fundamental theories of various methods of immunodiagnosis. Professor Ramon of the Institut Pasteur presented a paper on the anatoxins, emphasizing the importance of the diphtheritic anatoxin, the present better method of obtaining it and the essential qualities of the product: the innocuousness, the intrinsic antigenic value and the immunizing action and the irreversibility. He praised the official decree in Italy, which makes vaccination compulsory in the primary schools for children aged 1 to 5 when diphtheria is prevalent endemically.

Professor Schilling of Berlin offered a communication on immunity in disorders due to protozoa with especial reference to malaria in children.

Professor Koller of the University of Frankfurt-on-Main spoke on immunity in spirochetoses, particularly in syphilis. He emphasized that in human syphilis there is no proof of an active immunity.

Marriages

CLAUDE HENRY FRYAR Oak Ridge, N. C. to Miss Lucie Sutton Hayes of Palmer Springs, Va. Nov. 29 1933

CHARLES DOUGLAS SAWYER Port Chester, N. Y., to Miss Ruth Partridge of Maplewood, N. J., Dec. 9 1933

HAROLD HERMAN FREEDMAN Freehold N. J., to Miss Marian Winters of New Brunswick, July 28, 1933

CLOYCE R. TEW, Raleigh N. C., to Miss Anna Rebekah Waaser of Mauch Chunk, Pa. Sept. 8 1933

CHARLES WESLEY MYERS, Indianapolis to Miss Marguerite Preston of Knoxville, Tenn., Nov. 28 1933

RAY EDWARD CURRIE Medical Lake Wash., to Miss Frances Eleanor Joseph of Spokane Sept. 10 1933

CHARLES KENNEDY CAREY Rushville, Ill., to Miss Geneva Strong at Mount Vernon, Dec. 10, 1933

JOHN TALBOT GERSON, Chicago to Miss Lorene Fredericka Mueller of Minneapolis, Dec. 2 1933

CARL CAUGHMAN SON, Columbia S. C., to Miss Alluwee Babb of Spartanburg Aug. 15, 1933

LEO SMITH, Pearson Ga., to Miss Dorothy Elizabeth Quilian of Milledgeville Oct. 25 1933

LEVI STEELY SILER Corbin Ky., to Miss Dorsie Pember-ton, at Jellico, Tenn., Oct. 7 1933

ISAAC RIDGEWAY TRIMBLE to Miss Margaret Price Brown, both of Baltimore, Sept. 16, 1933

SOUREN H. TASHJIAN, Seattle, to Miss Margaret Cahalan of Yakima, Wash., Nov. 4 1933

OREN C. TARBOX to Miss Edythe Pearl Howe, both of Oneonta N. Y. Aug. 26 1933

EVON WALKER to Mrs. Leota Montgomery McVee, both of Ottumwa, Iowa, Sept. 6, 1933

JAMES ALLEN SMITH Macon, Ga. to Miss Sarah Jennings of Thomasville Oct. 12 1933

JOSEPH MCCRARY Bold Spring, Tenn., to Mrs. Azalee Reynolds in December 1933

WARDE BAUNTON ALLAN, Baltimore, to Miss Angelica Peale Iglehart, Dec. 2 1933

NORMAN W. GILLESPIE to Miss Mildred Nicholson both of Boston Oct. 26, 1933

WILLIAM C. KEYES to Miss Emma Filsinger, both of Bellingham Wash. recently

ROBERT G. SMITH to Miss Mary Poly both of Columbus, Ohio, recently

WALTER S. GRISWOLD to Miss Jessie Reeves both of Seattle, Aug. 20, 1933

Deaths

George Paul Marquis, Chicago, Northwestern University Medical School, Chicago, 1892, member of the Illinois State Medical Society, the American Academy of Ophthalmology and Oto Laryngology and the American Laryngological, Rhinological and Otological Society, fellow of the American College of Surgeons formerly assistant professor of laryngology and rhinology at his alma mater veteran of the Spanish-American War attending otolaryngologist to St. Luke's Hospital, aged 65 died, Dec. 22, 1933, of tuberculosis of the large intestine

Matthew Kollig, Saginaw, Mich., University of Michigan Medical School Ann Arbor, 1907, member of the Michigan State Medical Society, past president of the Saginaw County Medical Society, fellow of the American College of Surgeons formerly instructor in anatomy at his alma mater and professor of anatomy George Washington University School of Medicine Washington, D. C., on the staff of St. Mary's Hospital, aged 52 died Nov. 28 1933

Matthew D. Fullingim, Denton Texas Fort Worth (Texas) School of Medicine, Medical Department of Fort Worth University, 1899, member of the State Medical Association of Texas past president and secretary of the Denton County Medical Society for two years city health officer of Denton and physician to the North Texas State Teachers College aged 60 died suddenly, Oct. 16, 1933, of heart disease

Courtney Perry Grover, Dayton Ohio Kansas Medical College Medical Department of Washburn College, Topeka 1904, member of the Ohio State Medical Association, fellow of the American College of Surgeons served during the World War, formerly on the staffs of the National Military Home Hospital and St. Elizabeth's Hospital, aged 52, died Nov. 29, 1933, of streptococcal pharyngitis and diabetes mellitus

George Graham Hunter of Los Angeles University of California Medical Department, 1906 fellow of the American College of Physicians councilor at large of the California Medical Association and past president of the Los Angeles County Medical Society aged 57 on the staff of St. Vincent's Hospital where he died, Dec. 12 1933, of a bullet wound inflicted by a patient

Lyman C. Broughton, Castile, N. Y. University of Buffalo School of Medicine, 1889 member of the Medical Society of the State of New York for many years county coroner health officer of Castile and Genesee Falls aged 65, died Nov. 19, 1933 in the Wyoming County Community Hospital, Warsaw, of arteriosclerotic heart disease

William Edward Denning, Worcester, Mass. University of Vermont College of Medicine Burlington, 1899, member of the Massachusetts Medical Society, fellow of the American College of Surgeons, served during the World War, formerly on the staff of the Worcester City Hospital, aged 61, died, Dec. 7 1933, of heart disease

William Leslie Munson of Granville, N. Y., Albany Medical College 1908 served during the World War, district state health officer state department of health, for many years president of the board of education of Granville, on the staff of the Glens Falls (N. Y.) Hospital, aged 48 died, Dec. 2, 1933 of pneumonia

Frank Crawford Story, Marion Ind. University of Georgia Medical Department, Augusta 1926, on the staff of the Veterans' Administration Facility formerly county health commissioner of Jenkins and Wayne County, Georgia aged 37 died Oct. 30, 1933, in a hospital at Indianapolis, of retroperitoneal carcinoma

Oliver P. Terry of West Lafayette, Ind., St. Louis University School of Medicine 1906 medical adviser with rank of professor in the department of biology Purdue University aged 51, on the staff of St. Elizabeth's Hospital, Lafayette where he died, Dec. 6, 1933, following an operation for duodenal ulcer

Francis Calistus O'Neill, Philadelphia, University of Pennsylvania School of Medicine Philadelphia, 1911 member of the Medical Society of the State of Pennsylvania aged 52 on the staffs of St. Christopher's Hospital for Children and St. Agnes Hospital where he died Dec. 8, 1933

Burpee L. Steeves, Salem Ore., Willamette University Medical Department Salem 1894, past president of the Oregon State Medical Society, fellow of the American College of

Surgeons, formerly mayor of Salem and lieutenant governor of the state, aged 65, died Oct 23, 1933

Frank R Moore, Florence, Colo., Columbus (Ohio) Medical College, 1885, member of the Colorado State Medical Society, past president of the Fremont County Medical Society, health officer of Florence, aged 69, died suddenly, Nov 27, 1933, of heart disease

Frederick William Knoll ♂ Reading, Pa., Jefferson Medical College of Philadelphia 1914, served during the World War, on the staff of St Joseph's Hospital, aged 47, died Nov 29, 1933, of hypertension, nephritis, cerebral sclerosis and heart disease

Herbert M Klein ♂ New York, Cornell University Medical College, New York 1928, aged 30, died Nov 26, 1933, in the Massachusetts General Hospital, Boston, of pulmonary embolus, following an operation for fusion of the vertebrae

Ray Russell Hetherington, Pittsburgh, University of Pennsylvania School of Medicine, Philadelphia 1916 member of the Medical Society of the State of Pennsylvania, served during the World War, aged 42, died, Oct 22, 1933, of coronary sclerosis

Rufus D Boss ♂ Wacousta, Mich., Columbian University Medical Department, Washington, D C, 1891 past president of the Clinton County Medical Society, on the staff of the Clinton Memorial Hospital, St Johns, aged 71, died Dec 4, 1933

Ralph Evans Runkle, Oklahoma City, Barnes Medical College, St Louis, 1899, member of the Oklahoma State Medical Association, aged 55, died, Nov 23, 1933 in the Oklahoma City General Hospital, of bronchopneumonia

Louis Eugene Barlow, Philadelphia, Jefferson Medical College of Philadelphia 1896, member of the Medical Society of the State of Pennsylvania, aged 67, died, Dec 8, 1933 in the Frankford Hospital, of heart disease

Patrick Henry Whalen, Buffalo, University of Buffalo School of Medicine, 1906, member of the Medical Society of the State of New York, aged 48 died, Dec 12, 1933, of cerebral hemorrhage and hypertension

William Louis Rost ♂ New York, Long Island College Hospital, Brooklyn 1909 on the staff of the Morrisania City Hospital, aged 51, died, Dec 4, 1933, in the Mount Sinai Hospital, of malignant hypertension

John T Shelland, Ada, Minn. Medical Department of Hamline University, Minneapolis, 1900 member of the Minnesota State Medical Association, aged 61, died suddenly, in November, 1933, of heart disease

Abraham Jacob Sumner ♂ Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1906, on the staff of the Beth Moses Hospital, aged 48, died suddenly Dec 2, 1933, of heart disease

William Nicol Stein ♂ Sherrandoah, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1894 aged 63 on the staff of the Locust Mountain Hospital, where he died, Nov 23, 1933, of pneumonia

Joseph Armour Wade, Fredericton, N B, Canada Medical School of Maine Portland, 1877, first medical officer for the western health district of the province of New Brunswick, aged 84, died, Oct 21, 1933

Leopold Heimann ♂ Evansville, Ind., University of Louisville (Ky.) School of Medicine, 1904 aged 51, for many years on the staff of St Mary's Hospital, where he died, Dec 7, 1933 of cerebral hemorrhage

Daniel Webster Sullivan, Passaic, N J University of Vermont College of Medicine, Burlington, 1896, aged 64, died Nov 28, 1933, of heart disease, Parkinson syndrome and chronic arthritis deformans

Joseph N Kiefer, Buffalo, University of Buffalo School of Medicine, 1906, member of the Medical Society of the State of New York, aged 52, died, Dec 15, 1933, of septicemia and heart disease

Samuel Steele, Chanute, Kan. Kansas City (Mo.) Medical College, 1896, aged 63, died Nov 18, 1933 in the Research Hospital, Kansas City, Mo., of arteriosclerotic cardiovascular renal disease

Joseph A Oliver, San Francisco, University of California Medical Department, 1889, member of the California Medical Association, aged 71, died, Oct 17, 1933, of arteriosclerosis

Joseph Marzano, Chicago, Loyola University School of Medicine, Chicago, 1931 member of the Illinois State Medical Society, aged 25, died, Dec 21, 1933, of pneumonia

Alfred Charles Nicholas Peterson, Worcester, Mass University of Pennsylvania School of Medicine, Philadelphia 1897, aged 65, died, Nov 6, 1933, of arteriosclerosis

Phreborn Grundy Paugh, St Louis Marion Sims College of Medicine St Louis 1899, served during the World War, aged 62, died, Nov 24, 1933, of heart disease

Carl W Kimery, Lerna III Barnes Medical College St Louis 1898, aged 64 died Nov 24, 1933 in the State Hospital, Jacksonville, of carcinoma of the liver

Jesse Edgington, Hood River, Ore., Kentucky School of Medicine Louisville 1879, formerly county health officer, aged 84 died, Nov 15, 1933 of chronic myocarditis

James McConnell Hubbard, Hickman, Ky., Missouri Medical College, St Louis, 1886 formerly county health officer, aged 70 died, Nov 29, 1933 of heart disease

Thomas Byron Kea, Adrian, Ga., Atlanta (Ga.) Medical College 1915 member of the Medical Association of Georgia aged 54, died Dec 5, 1933, of heart disease

August Henry Malm, Princeton, Ill., Barnes Medical College St Louis, 1895, since 1904 county coroner, aged 64, was found dead, Dec 4, 1933 of heart disease

Horace H Prefontaine, South Durham, Que., Canada, Laval University Medical Faculty, Montreal, 1890 aged 68, died Oct 12 1933 of heart disease

Sheridan P Manship, Philadelphia University of Pennsylvania School of Medicine Philadelphia, 1890, aged 65 died Dec 14 1933 of acute nephritis

Alfred G Smith, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1900, aged 54 died, Nov 27 1933 of chronic myocarditis

William Lawrence Dunn, Oakland, Calif University of California Medical Department 1897, aged 58 was found dead Nov 24 1933 of heart disease

Thomas Simpson Pryse, Dawson, N D., University of Louisville (Ky.) School of Medicine 1894, aged 61, died in October 1933 of heart disease

Ninian Wildridge Woods, Braxfield, Ont., Canada L.R.C.P., Ireland 1887, M.R.C.S., England 1887 postmaster aged 73, died Oct 31, 1933

Raymond Wallace Anderson, New Hamburg, Ont., Canada, University of Toronto Faculty of Medicine, 1904, aged 50 died, Sept 30 1933

Joseph D McCarter, Beaver Falls, Pa., Jefferson Medical College of Philadelphia 1883 aged 77, died in December, 1933 of cerebral hemorrhage

Benjamin H Kirk, Union Star, Mo (licensed Missouri, 1884) Civil War veteran, aged 91 died, Nov 20 1933 of pulmonary emphysema

Albert Habermaas ♂ St Louis Marion-Sims College of Medicine, St Louis 1896 aged 61 died, Nov 20, 1933 of cerebral hemorrhage

Harry Wishart Keith, Enderby, B C, Canada, McGill University Faculty of Medicine, Montreal, Que., 1896, aged 60 died Oct 22, 1933

John Shelby Moremen, Louisville, Ky., Kentucky School of Medicine Louisville, 1890 aged 68 died, Nov 30, 1933 of angina pectoris

James B McPike, Smileyville, Mo College of Physicians and Surgeons Keokuk, Iowa, 1879 aged 76 was found dead, Nov 19, 1933

Joseph Thomas Poock, Hoboken, N J Baltimore Medical College 1890 aged 73, died Nov 13, 1933 in St Mary's Hospital

Samuel Henry Ward, Los Angeles Chicago Homeopathic Medical College, 1896 aged 59 died Oct 29, 1933, of angina pectoris

A P Massengill, Halls, Tenn Memphis Hospital Medical College 1907 aged 61 died Nov 29, 1933, of heart disease

Charles R Long, Pierceton, Ind., Detroit Medical College 1880 aged 82 died Nov 23 1933, of cerebral hemorrhage

Daniel J Halbrook, Formosa, Ark (licensed in Arkansas in 1903), aged 61 died Nov 28 1933, of heart disease

Chambers J Penn, Piketon Ohio (licensed, in Ohio in 1896) aged 81, died Nov 21, 1933 of heart disease

Edward Pearce, Marshall, Ill Chicago Medical College, 1878 aged 83, died Nov 21, 1933, of arteriosclerosis

Charles M Oughton, Evanston, Ill Rush Medical College, Chicago, 1884, aged 71 died Dec 8 1933

Josephus W Benadom, Monticello Iowa (licensed, Iowa, 1887) aged 90, died Dec 5 1933

Bureau of Investigation

MICRO-DYNAMICS

One of the Outgrowths of the Electronic Reactions of Abrams

Every physician who has practiced for ten years or more remembers the gigantic piece of pseudo scientific hokum that was brought into existence by the most polished charlatan of the century, Albert Abrams. This man and the followers of the cult that he developed claimed that it was possible by means of some pieces of electrical hocus-pocus that Abrams put on the market and leased at a high price, to diagnose from a drop of dried blood, or even from the autograph of a person, the ailment from which that person was suffering. Then the diagnosis having been made, the patient was switched on to another Abrams machine to cure the condition by alleged vibrations. Disciples of the cult reaped a golden harvest diagnosing disease where it did not exist and then charging the victims a round price for curing the non-existent ailment. Abrams named his cult the "Electronic Reactions of Abrams" shortened for commercial purposes to 'E R A'.

Now, there is being pushed to the medical profession a device that, if the exploiters are to be credited, is still more marvelous than any of the wonders called from the vasty deep by Abrams. It is called the "Micro Dynameter" and is put out by a concern known first as the Electronic Research Laboratories and now as the Ellis Research Laboratories, Inc. The man back of the concern seems to be Mr F C Ellis, who claims to be a graduate of the University of Wisconsin, Electrical Engineering, of the Kansas State College, General Science, and of the Finlay Engineering College. He has described himself as a consulting engineer. The only information regarding Mr Ellis' abilities in the electrical field of which we have any evidence is the fact that in 1925 his name headed a committee of three which declared that it had examined the "Tricho" apparatus and concluded that "all of the necessary precautions have been taken in its construction to safeguard the patient from exposure to undesirable rays". Physicians will remember that the Tricho device—an X-ray machine for depilation and one of the most viciously dangerous pieces of apparatus ever put into the hands of beauty-parlor operators—has been responsible for innumerable cases of X-ray burns, atrophies, telangiectases, ulcers and, in some cases, cancer.

The Bureau of Investigation has made no examination of the mechanics of the Micro-Dynameter. This article will be confined to a discussion of the background on which the device is projected, and of the claims made for it. There is a tendency on the part of the medically untrained to assume that whenever a fantastic piece of pseudo-medical apparatus whose use is predicated on a preposterous theory is commercially exploited, it becomes the duty of the organized medical profession to check and recheck such apparatus by technical means to determine whether or not the claims made for it are true. The facts are of course that in all such cases the burden of proof lies with the man or concern that is making money by promulgating the theory and exploiting the machine. Surely no one would hold that the American Astronomical Society would be under obligation to carry out extensive spectroscopic investigations to disprove the claim that the moon is made of green cheese. No sensible person believes that it is incumbent on the medical profession to carry out a series of experiments to prove or disprove the belief, widely held by some, that the left hind foot of a rabbit caught in a churchyard in the dark of the moon is a therapeutic agent of potency and respectability.

THE BACKGROUND

In 1923 Mr Ellis' concern was known as the Electronic Research Laboratories, it claimed to make precision instruments for the diagnosis and treatment of disease. At the time Mr Ellis was putting out *Bulletin No 1* entitled 'Report on "Electronic Diagnosis and Treatment of Disease"'. In the opening pages of this report he stated:

'Science is just entering the field of vibrations

Each form of diseased matter in common with other forms of matter has its own characteristic vibratory rate and gives off energy of individual wave form

'When a healthy person is properly connected by wires to a certain device containing a drop of blood extracted from a diseased patient then under certain conditions definite physiological effects are produced upon the abdomen of that person. This is a readily demonstrable fact. These manifestations are the product of the action of disease emanations from the blood sample.'

There was much more of the same tenor, with tables and graphs, all mysterious and impressive. On the well-known thesis that the unintelligible appeals to the unintelligent, the bulletin doubtless impressed a certain class. The sum and substance of Mr Ellis' *Bulletin No 1* seemed to be that Albert Abrams' theories were all right but his practical applications were rather crude. Mr Ellis closed the *Bulletin* with certain conclusions, the first of which was:

The existence in diseased blood of radiant energy of wave like character has been established.

Other conclusions were to the effect that the Abrams theories of cure had been disproved, but Mr Ellis had enunciated the correct theory, that the defects in the Abrams apparatus for electronic diagnosis and treatment had been revealed, but that Mr Ellis had developed superior apparatus.

The L D Rogers Testimony—Thus, it will be remembered, was in 1923. In September, 1924, Mr Ellis sent out on his own stationery as 'consulting engineer' a mimeographed 'release' to editors describing the alleged work of Dr L D Rogers 'in measuring the cancer wave,' which, according to Mr Ellis, 'lies in a new band of radio frequencies'. L D

Two of Mr Ellis diagnostic instruments—the Indicator and the Intensity Gage.

Rogers will be remembered by many readers of this department of THE JOURNAL as the exploiter of "Auto-Hemic Serum," as the one-time dean of the National Medical University, a "sun-down" institution of ill repute as the advertiser of an alleged Japanese treatment for tuberculosis, etc. Mr Ellis assured the editors that, according to Rogers' findings, "cancer acts as a miniature broadcasting station." Let us quote from one paragraph of the story:

'In the test Dr Rogers used as a subject a woman about 45 years of age. Says Dr Rogers: "I tried out different samples of her blood at different times—during every test we got most pronounced cancer wave radiations. On one occasion we took the sample of blood to Mr Ellis inventor of the delicate indicator used in this test. Without any suggestion of any kind as to the nature of the wave length he measured it correctly as cancer and also located it in the right breast."

Substitute the name of "Albert Abrams" for that of "Mr Ellis" in the quotation just given, and it might have been taken almost direct from the old Abrams ballyhoo.

'Feeding the Sick Atom'—In 1924, also, Mr Ellis was sending out a little pamphlet, obviously intended for the general public, entitled "Feeding the Sick Atom in Disease." The opening paragraph under the chapter heading "Health and Disease Waves" stated that the booklet was 'an account of a new and remarkable method of protecting and combating disease in sick people.' It went on to elaborate by stating that "man is an electrical machine made up of tiny batteries" and that when "the batteries in the human plant" run down, it produces the condition we call disease. Then:

To overcome such a condition the batteries of the body need recharging and this may be done in a simple manner.

Mr Ellis then dwelt on the improved apparatus that he had devised for electronic diagnosis, thus

When a healthy human being (Detector) is properly connected to a device called an Indicator containing a drop or so of diseased blood from a patient the disease waves can be tuned into

On another page of the same booklet an electronic "treatment" with an Ellis machine was described. It was stated that in taking the treatment the patient sits comfortably in a chair with his feet on a metallic plate while electrodes are either held in the hands or applied to certain parts of the body. Wires leading from the treatment apparatus were said to "carry a flow of the elements which are needed by the patient and which have been liberated through the destruction of a metal by incandescence and applied under proper low potentials to the patient." It was emphasized that this Ellis treatment was a very different thing from what the public usually considered "electrical treatment" and that no current could be felt.

However a pleasant sensation of warmth beginning at the extremities and gradually pervading the whole body is usually experienced and this is accompanied by an unmistakable increase in vigor and mental clarity and a getting well feeling which builds up and carries the patient forward to health from the first treatment.

The Indicator (on the left) and Intensity Gage (on the right) in use in making a diagnosis from a drop of blood. This picture according to Mr Ellis is one illustrating a convenient set up for diagnosis. The drop of blood (on paper) is put on the far end of the Indicator which is connected at one end with an electrode held to the forehead of the Detector (a healthy subject) and at the other end with the Intensity Gage which in turn is connected to a metallic plate on which the Detector stands. By percussing the abdomen of the Detector the physician acquainted with the mysteries of Micro Dynamics determines the pathologic state of the patient from whom the drop of blood was taken.

The booklet then went on to explain that Albert Abrams was the originator of electronic diagnosis and treatment, but that as he was "primarily a physician, not a physicist" his apparatus was admittedly rather crude. It was a logical sequence, it continued, that expert physicists—such as Mr Ellis—should be turned loose on the problem. This was done, with the result that instruments of greater refinement and giving a "fuller measure of success in diagnosis and treatment" had been brought about. Then comes in the closing paragraphs the admission that these new instruments, "the result of a long and scientific research" had been developed by the Electronic Research Laboratories!

The Indicator and 'Intensity Gage'—In 1924 Mr Ellis already had some of these 'new instruments' on the market. One was known as the 'Indicator'. Its function was to fix "as stationary electrical waves" the "electronic emanation from matter such as diseased blood." Another device was the 'Intensity Gage'. The two instruments sold for \$300.00, the 'Treatment Apparatus' was \$350.00. The Intensity Gage we were told, unlike the Indicator, which measured the length or

base of an electronic wave," was used "for the purpose of measuring the amplitude of such a wave." These two devices, the Indicator and the Intensity Gage, seemed to be used in much the same way that Abrams used his diagnostic mystery boxes. In use, a healthy subject, known as the "Detector," stood on a metallic foot plate that was connected by wire to the Indicator. The Indicator was connected by wire to the Intensity Gage. The Intensity Gage was connected by wire to an electrode which the healthy subject (Detector) held against his forehead while his abdomen was percussed and the "diagnosis" made!

The Seven Basic Diseases—At this stage of Mr Ellis' investigations he had expressed the opinion that there were seven definite "disease emanations" whose "frequencies" lay "between the limits 37,500,000,000 and 150,000,000,000 cycles per second." Probably realizing from Abrams' experience the possibility of being laughed out of court if he attempted to name his seven fundamental disease forms, Mr Ellis expressed the opinion that "the naming of individual wave forms indigenous to diseased blood is unsatisfactory." But the patient who had to pay the bill for a "diagnosis" might be expected to demand information less ethereal than the statement that he was suffering from electronic vibrations whose frequencies were let us say 55,343,000,000 cycles per second. To meet this, pragmatically Mr Ellis suggested—in a pamphlet devoted to "Operating Instructions" of his "Indicator" and "Intensity Gage"—that "of course it may be necessary from the patient's standpoint to give diagnostic findings in terms of the common disease names." He therefore gave the following tabulation of the seven "basic diseases":

HALF WAVE LENGTH	DISEASE	SETTINGS OF INDICATOR	
		SLIDE 'L'	SLIDE 'R'
1	Conorrhea	1	1
2½	Sarcoma	2½	2½
3	Carcinoma	3	3
4	Congenital Syphilis	4	4
5	Acquired Syphilis	5	5
7	Streptococcus	7	7
8	Tuberculosis	8	8

How reminiscent this is of Abrams. He it was who reported finding carcinoma, syphilis and many other serious conditions in patients in whom ordinary M.D.'s could find no organic trouble. In fact diagnosing syphilis in certain husbands and wives who were quite free from that disease brought Abrams legal grief. As a result he suggested to the followers of his cult that they substitute for what he had been calling congenital or acquired syphilis the euphemism 'Congenital or Acquired Diminished Resistance'.

Selecting Diet by Radio—By 1925 Mr Ellis had extended his field of operations. He had brought out a "Food and Remedy Test Set"—price \$85.00. This was, as Mr Ellis advertised, to make it possible for patients to have their 'Remedies and Diet Selected by Radio'. The Food and Remedy Test Set was a shallow case or box containing between two and three hundred short metal cylinders standing vertically. Small glass vials slipped loosely into the cylinders. The food, condiment "tissue salt," "protein or pollen," beverage or "drug or serum" to be tested "by radio" was placed in a vial which was put into one of the metal cylinders ("and so is shielded from all other specimens"), then a hollow electrode which would fit into the metal cylinder was put in position over the vial and the electrode was connected with Mr Ellis' "Indicator." This, in turn was connected by wire with Mr Ellis' Intensity Gage which also in turn, was connected by wire with the person ("Detector") who was standing on a metal plate holding the electrode from the Intensity Gage to his forehead while the Ellis disciple percussed the abdomen of the "Detector" and thus solved the mystery of the food, "tissue salt," "drug or serum," etc.

In 1926 Mr Ellis was advertising a "Laboratory Service" and sending physicians a mimeographed letter with which was included a buff envelope bearing the name and address of the "Electronic Research Laboratories" with the statement printed on it "Specimen of Human Blood Submitted for Electronic Examination by Dr. ———." In the buff envelope was a black envelope (presumably to keep out any stray radio waves) and in it was a piece of white test paper on which the blood

specimen was to be put and then the whole mailed to Mr Ellis. The mimeographed letter gave the explanation of the "test" services offered.

(1) *The Disease Test* includes determination of radiations from diseased blood specimens associated with basic diseases such as Carcinoma, Syphilis, Tuberculosis, Streptococci infections, Gonorrhea, Syringia and others if indicated in accordance with the well known methods published by these Laboratories and previous calibrations of the Ellis Precision instruments from known disease sources. As has been demonstrated these are the most sensitive present methods for this work.

(2) *The Food and Remedy Selection Test* includes a determination of (a) What substances such as foods, stimulants, chemicals, etc. used by a patient are incompatible and act to increase the disease energies in his blood and (b) What substances contain elements needed by the patient which will reduce or nullify his disease energies as indicated in the blood radiation analysis.

Cow Curing—In 1926, also, Mr Ellis was describing how tuberculous cattle were being diagnosed and cured with his machine. One sick bossy was diagnosed on June 26 as "Tuberculosis, 100%, streptococci infection 51%". She was given Ellis treatments and then on July 7 again put on the diagnosis machine. This we are told recorded "Tuberculosis 0, strep 8½%". The report closes with the statement: "On July 8 another abscess broke and pus exuded from eyes and nose, cleared away, appetite voracious."

About this time, too, Mr Ellis seems to have named his "Treatment" machine the Raydion. He also combined an "Indicator," an "Intensity Gage" and a "Food and Remedy Test" into one unit and christened it the "Quantometer." In addition, he advertised a line of dehydrated food products with a *Bulletin* (No 19-B) detailing the virtues of certain foods thus:

Peaches—Eliminate bile and poison in the kidneys

Yellow Turnip—Very cooling to the nerve and brain centers

Mushrooms—Nerve and brain food

Irish Moss—Has remarkable value in the elimination and dissolving of goiter and is a natural food for the restoration of hair to its natural color and in promoting the growth of the same.

Mr Ellis' Food and Remedy Test Set. According to Micro-Dynamics, certain drugs, chemicals, vaccines, medicines, foods and other substances have been found to radiate energies similar in intensity to those of disease sources and to have wave lengths which are similar or close multiples thereof and which will cause abdominal reactions similar to those of disease.

Mr Ellis, in a "Technical Number" of one of his *Bulletins*, declared that the effects of treatment by his machine the "Raydion," had been observed with the ultra microscope by watching the dispersion and movement of the protein particles in the blood.

When these particles lose their electric charge they coagulate and precipitate in and clog the capillaries and produce degenerative processes of disease. Following treatment on the Raydion the protein particles have been observed to be dispersed again due to restoration of normal electric charge—replacement of missing electrons on the particles.

It was about this time that Mr Ellis began to quote McDonagh and his theory. Dr McDonagh of London, England, has established what bids fair to become a cult. It appears from the intricate and involved theories that he has built up around a private nomenclature, that Dr McDonagh holds that practically all pathologic and therapeutic action consists in changes of the condition of the colloids—mainly proteins—of the body, which, he claims, in health are in an optimum state of dispersion. Hence his slogan: "There is

In 1922 Mr Ellis even invaded the veterinary field. Here is shown a cow being tested for tuberculosis.

only one disease'—namely, a change of the condition of the colloids. So far as we know, Dr McDonagh is quite unaware of Mr Ellis and his mechanical apparatus for diagnosing and treating disease. In fact, Dr McDonagh apparently is interested in the prescribing of certain proprietary remedies of secret composition known by such peculiar names as 'SUP 36,' 'SUM 36,' 'Antrypol,' etc. Apparently the one angle of McDonagh's theories that is of particular interest to Mr Ellis is that McDonagh has reduced all disease from seven basic pathologic states to one.

MICRO-DYNAMETER

The apparatus that Mr Ellis is exploiting at the present time is a great improvement, of course, on the Indicator, Intensity Gage, Food and Remedy Test Set, Radion, Quantometer, etc. It is known as the Micro-Dynameter and as Mr Ellis points out has "an unusually impressive appearance." The advantage of the latest piece of apparatus to come from the Ellis Research Laboratories is that it apparently makes the diagnosis and treatment of disease purely mechanical. No longer is there any need of the healthy subject ("Detector") having to stand on a metallic plate and have his abdomen percussed in order to learn what disease emanations there are in a blood specimen or the nature of the vibrations there may be in a vial of spinach.

Now the entire problem has been reduced to its lowest common denominator. Mr Ellis describes his Micro-Dynameter as a "New Mechanical Detector for Diagnosis and Precision Therapeutic Generator." The essential part of the Micro-Dynameter, so far as the physician who is supposed to use it is concerned, is the "Detector Scale," which is a little over a foot wide, has a zero mark in the center, and ranges from 150 points on either side of zero—negative to the left and positive to the right. Readings are said to be made by means of a spot of light casting a vertical narrow shadow which travels along the scale "under the impulse of minute electric currents generated by a patient's body." Each of the 150 divisions, both negative and positive, are said to be adjustable up to 1,000 units. The normal human body, instead of registering zero on the scale, is said to register 50 or, in Mr Ellis' figures, 50,000 to the right (positive) of zero, as he puts it. "This is the zone of Health and maximum Vitality." The range to the left from 50,000 to zero is said to take in most of the "chronics," while in the range to the right, 50,000 to 150,000, come the "acute" cases.

In making a diagnosis, the patient is attached to the Micro-Dynameter by two electrodes, one a metallic plate on which he stands in his bare feet, the other a metallic rod that he holds in his hands. Then the current is turned on and a narrow black line should appear at zero. Another switch is thrown and the line begins to move slowly and it comes to rest on a certain mark to the right of the zero point 'which your patient can see and understand'. This according to Mr. Ellis is said to reveal 'in one single reading the summation of all disease factors going back to those of heredity. Or, to put it in Mr. Ellis' own modest phrase expressed in black-faced type, the Micro-Dynameter is 'the first true therapeutic gauge in history' and 'a perfected scientific mechanical detector for diagnosis'.

Mr. Ellis then lists a number of "diseases"—as they are quaintly called by ordinary physicians—and the markings that are shown on the Detector Scale of the Micro-Dynameter correspond to these diseases. Thus

Advanced Diabetes with Obesity	3 000
Heart prostration, extreme exhaustion	4 000
Cancer	9 000
Melancholia high blood pressure	12 000
Tuberculosis	15 000
Apoplexy	16 000
Neurotic	17 000
Asthma	18 000
Nervous breakdown	22 000
Anaemia	27 000
Sacro-Iliac strain	33 000
HEALTH	50 000
Deafness cataract	59 000
Syphilis	77 000
Acute Gonorrhoea	91 000
Acidosis	122 000
Insanity	141 000

From this presumably incomplete table, it will be seen that good health lies somewhere between a sacro-iliac strain and deafness and cataract. It appears, further from Mr. Ellis' book that a patient's "polarity"—determined by the Micro-Dynameter in connection with another of Mr. Ellis' devices, the "Polarimeter" may depend to some extent on where he lives. We read, for example

In New York a large group of people measured positive in every single case and no two were alike variations ranging from 3 divisions up to 1800 divisions to the right of 0. In Chicago the proportion is very close to two positives to one negative and likewise wide differences between the degree of displacement from 0 between individuals. In Des Moines Iowa a group split exactly even between positive and negative.

From this it would appear that Des Moines, Iowa would be the ideal place to live, were it not for the further fact that Mr. Ellis says that "this factor is influenced by the seasons and the weather."

Another chapter in Mr. Ellis' book on Micro-Dynamics deals with the localization of disease after it has been diagnosed. Mr. Ellis would like to resolve all diseases into one or, as he puts it, "the reduction of all diseases to simple unity would constitute the greatest scientific classic." But he admits that this is "just now relatively a big step to take." In fact, he thinks that "the proposal is probably 25 years or more ahead of the world," because "the patient still demands to know the name of his ailment." Mr. Ellis still thinks, though, it would be far better for everybody concerned if one could reduce the thing to two terms, Health and Disease and instead of trying to find *what* a person has, determine *where* he has it.

Mr. Ellis claims for the Micro-Dynameter the following advantages over the older instruments

- 1 A complete examination which formerly might have required an hour can be made by this new method in from 5 to 10 minutes.
- 2 The efficiency of detection is increased from 5% to approximately 100% due to the fact that the human element is ruled out completely and the detections are made by means of the sense of sight instead of the unreliable senses of touch or hearing.
- 3 Technique is utterly simple due to the automatic working of the instrument.
- 4 More confidence on the part of the patient is assured by the visual readings which the patient may also read and understand [Italics ours—Ed.] by reason of correlation with his symptoms and experience.

Mr. Ellis does, it is true, throw in as a suggestion that after this 100 per cent efficient diagnosis has been made, "physical examination may be employed to verify these findings." One wonders why.

The Micro-Dynameter is also used in the treatment of disease. It is, in fact, "a Precision Therapeutic Generator." After

the instrument has been used to make the test of "vitality" and then the patient's "polarity" is measured, "the calculation of the treatment is made with the aid of a blue print of curves, which are calibrations of the instrument." A picture is given showing a patient with hepatic insufficiency receiving treatment from a Micro-Dynameter. The patient grasps one electrode with both hands, a flat electrode is placed over his liver, and his feet are contacted with a foot plate. The current is turned on and the hepatic insufficiency disappears?

The Micro-Dynameter is also recommended as having "particular application to the problem of Special Analysis" and, as such, will doubtless interest osteopaths and even chiropractors, for it is said to record spinal subluxations.

This story has been a long one, but it has been necessary in order that the medical profession may have a clear understanding of the background, medical and otherwise, on which Micro-Dynamics is predicated. Mr. Ellis has, in a pamphlet recently issued attacking the American Medical Association when considerable umbrage over the fact that the Bureau of Investigation of the American Medical Association in answering inquiries about Micro-Dynamics, has stated that it knew of no evidence from scientifically respectable sources to sustain the claims made for the Micro-Dynameter. As indicative of

This is Mr. Ellis' Chart No. 1 localizing certain diseases—mainly in the As Bs and Cs—by means of the diagnostic set up already illustrated. This chart is reminiscent of the ones put out by Albert Abrams.

Mr. Ellis tactics, he reproduces in his booklet a letter which a chiropractor wrote to the Bureau of Investigation about the Micro-Dynameter. The Bureau of Investigation answered the letter briefly, as follows

Dear Sir—In our opinion, there is not a scintilla of evidence from scientifically respectable sources to sustain the fantastic claims made for the Ellis Micro-Dynameter.

Mr. Ellis publishes the chiropractor's letter and the Bureau of Investigation's reply, and in a comment implies that he is surprised that the Bureau of Investigation should stand ready to serve a chiropractor. The Bureau of Investigation answers inquiries from all laymen—the butcher, the baker and the candlestick maker. It has given information concerning

nostrums and quackeries on a few occasions to chiropractors. The Bureau, however, has never found it necessary to employ a chiropractor to write a decoy letter.

The peculiar theories and still more peculiar device of Mr Ellis would probably never have become of sufficient importance to warrant a detailed description of them had it not been for the fact that Mr Ellis' device has been given a quasi respectability by having been exhibited at the convention of the Inter-State Postgraduate Medical Assembly at Cleveland. The further fact that Mr Ellis' device is advertised in *Clinical Medicine and Surgery* may also mean much to him but the profession is fairly well aware of the fact that this particular journal carries advertisements of many dubious products.

While Micro Dynamics is essentially a further extension of the preposterous theories of Albert Abrams, there is this difference. Albert Abrams was a physician and a charlatan; his devices were electrically and mechanically crude to a degree. Mr Ellis is merely an electrical engineer without medical knowledge or training who apparently believes that he has reduced the diagnosis and treatment of disease to the simplicity of a nickel-in-the-slot gum-vending machine. The ability to sell such fantastic devices as Perkins' Tractors, the Abrams machine and the Micro-Dynamometer are actually a much greater indictment of that part of the medical profession that buys them than they are of the individuals whose names these devices bear.

Correspondence

ULCERATIVE COLITIS

To the Editor—Recently two articles on chronic ulcerative colitis have appeared in *THE JOURNAL*. The former of the two was written by us (November 4, p. 1462), the latter, by Dr Moses Paulson (November 25, p. 1687).

The altercation between Dr Paulson and us is well known to those who are interested in gastro-enterology. To say that the dispute is of no importance to us personally would be to assume an indifference which we do not feel. Nevertheless, we forbore to mention it in our article, for it is not absorbing to those who are not specialists in the field concerned, and it might well result in disservice to the sick. Here we carry the controversy no further than to refer those who are interested to our published work. Such readers will be able to judge whether Dr Paulson's partial direct quotations and his indirect quotations of us have always been of sufficient length to give an accurate impression of what we have stated and done.

The reason for this note is only that we believe the destructive character of Dr Paulson's paper might result in leading some physicians, who see only an occasional case of ulcerative colitis, to believe that no aid can be given. We have demonstrated the contrary.

We published the report of our work as soon as we thought we had ascertained something that would be of value at the bedside. Of the fact that we have modified our ideas as we gained more knowledge we are proud rather than apologetic. Dr Paulson is correct in saying that etiology must not be confused with therapy. We have not so confused them. We have recognized that gaps might exist in our concepts of etiology, and in attempts to fill these gaps we have extended our studies into all manner of intestinal ulceration. But we have applied what we knew, and have followed our patients sufficiently long to be sure of our results. These results have engendered in our minds nothing of the despair to which Dr Paulson confesses.

Rochester, Minn.

DIAGNOSIS OF AMEBIASIS

To the Editor—In reference to the diagnosis of amebic dysentery, as outlined in the article by Dr Kano Ikeda of St Paul in the Dec 16, 1933, issue of *THE JOURNAL*, I venture to state that his conclusions regarding the laboratory diagnosis are not borne out by the experiences of those who have had an opportunity to study the intestinal amebias of man.

He says: "While, therefore, I follow the teaching of the authorities that the finding of red blood cells within the vegetative form of amebas and the demonstration of the four nucleated cysts should constitute the final diagnostic criteria of *Endamoeba histolytica*, I feel that, in experienced hands, a positive diagnosis without either of the two, may be justified, at least in the face of an outbreak such as has been witnessed."

In the first place, the finding of the vegetative form is not easy unless one can procure the specimens directly from the ulcerations through proctoscopic examination. Secondly, the differential diagnosis of the vegetative form of *Endamoeba histolytica* and *Endamoeba coli* is not easy. Possibly the finding of the red cells within the cytoplasm in the case of the former, and the finding of foreign bodies, bacteria, and so on, in the case of *Endamoeba coli*, are good diagnostic differential points, but, after all is said and done, the true diagnosis of this disease must be made by finding the cystic forms. Differences between the cysts of *histolytica* and *coli* are very striking. I have found in this country that but few laboratory workers are performing routine examination of stools for the demonstration of the cystic forms by staining methods. Thirdly, it is manifestly unscientific and unwarranted to make a diagnosis simply because we are facing an outbreak of supposed amebic dysentery in certain communities. On the face of it, this is very poor advice to be given by the laboratory to the general profession.

In my studies at the Hamburg Institute of Tropical Medicine under Professor Reichenow, it was emphasized that the finding of cysts was the only true criterion for the laboratory diagnosis of this disease. It should be used as a routine method in all laboratories.

It is imperative that in stool examinations a routine staining process be carried out in all suspected cases of amebic dysentery. Once the observer becomes acquainted with the characteristics of the cysts of these two forms, no great difficulty occurs in making a laboratory diagnosis.

The staining method is as follows:

1 Fix in a mixture of 2 parts of saturated aqueous solution of corrosive mercuric chloride and 1 part of alcohol, from twenty to sixty minutes.

Put specimen on cover glasses, not slides. Smear needle float on surface of petri dish containing fixative, face downward, then turn them around with forceps, face upward. They sink.

2 Pour off mercuric chloride-alcohol, put back into bottle. Pour on iodo-alcohol (alcohol 70 per cent and tincture of iodine enough to give a light port wine color).

3 Let stand from twenty to thirty minutes.

4 Pour off. Seventy per cent alcohol one hour or longer (from twenty-four to forty-eight hours).

5 Pour off. Iron alum, 4 per cent, one hour.

6 Pour off. Stain one hour in Heidenhain hematoxylin, 1 per cent. Should be ripened four weeks. Wash in water. (Heidenhain hematoxylin is made by dissolving 1 Gm of hematoxylin in 10 cc of 95 per cent alcohol and diluting to 100 cc with distilled water. It should not be used for at least four weeks.)

7 Differentiate with 2 per cent iron alum in dish with cross marked on bottom to designate one, two, three and four minutes' immersion. Take out the thinnest for one minute, thicker, more time.

- 8 Place in water one, two, three and four minutes
- 9 Wash in running water for twenty minutes
- 10 Place in small bottles the various ingredients for the final staining

Sixty per cent alcohol
 Eighty per cent alcohol
 Eighty per cent alcohol
 Ninety-six per cent alcohol
 Absolute alcohol
 Xylene
 Xylene
 Mount in balsam

For the examination of fresh material, in searching for the vegetative form it is necessary only to use a small amount of

water (1 part camphor, 2 parts alcohol, 200 water, filtered) 250 cc, distilled water 700, acetic acid 65 cc. A hazelnut size piece of stool is rubbed with from 2 to 5 cc of water, then add 50 cc of the foregoing solution and shake. Then filter through a gauze filter. Then it is put into a separatory funnel. Add 15 cc of ether, shake, removing the stopper two or three times and then let stand. In a few seconds the ether impregnated detritus goes into the upper layer. In the lower layer are found the cysts and eggs of worms, which one can concentrate by centrifugation for a few minutes. The sediment can be examined fresh or stained.

In addition to *Entamoeba histolytica* and *Entamoeba coli*, the staining method for cysts will show the characteristic *Entamoeba tenax*, *Entamoeba bütschlii*, *Endolimax nana* and *Dientamoeba fragilis* any one or several of which may be present in any one specimen.

The accompanying chart of the characteristics of these various forms is the composition of Professor Reichenow of the Institut für Schiffs und Tropenkrankheiten of Hamburg, Germany.

R B H GRADWOHL M.D., St. Louis

THE HAZARDS OF DRY CLEANING

To the Editor—I read your comprehensive and timely editorial "The Hazards of Dry Cleaning" (*THE JOURNAL* Dec 16 1933 p 1970) with a great deal of interest and benefit, and may I say that I second all of the suggestions contained in it.

One phase of the subject however, I believe needs further emphasis. This has to do with commercial dry cleaning.

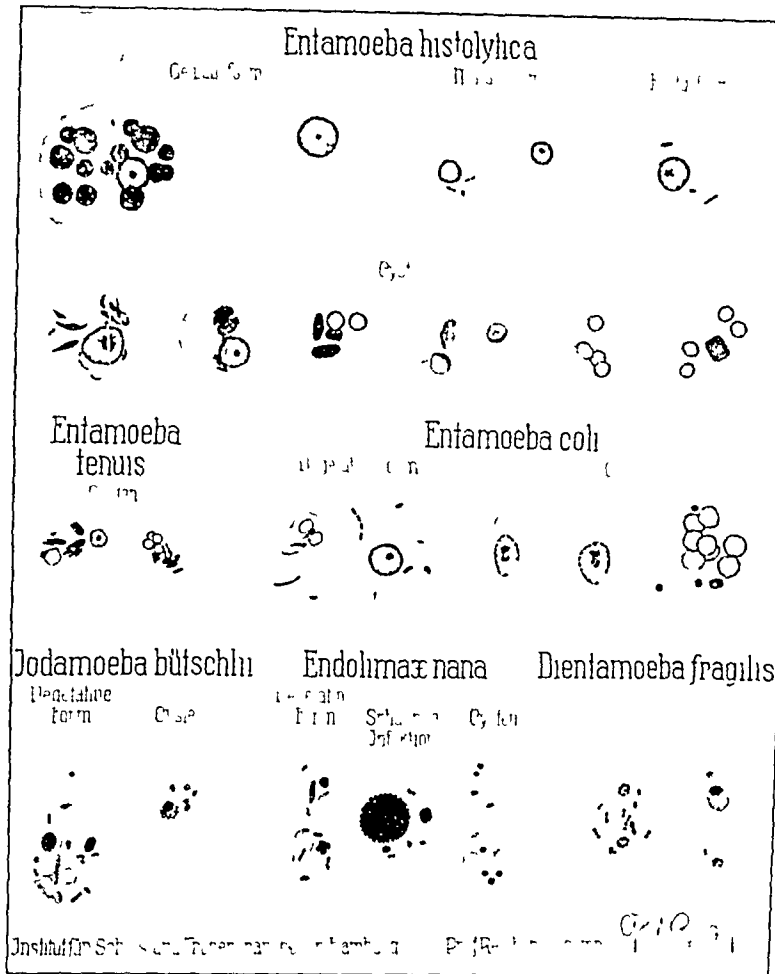

Since the introduction of carbon tetrachloride and trichlorethylene as a general solvent in the dry cleaning establishments, I have noted cases of dermatitis of varying severity which followed the wearing by women of clothing recently cleaned in these establishments. In all the instances observed there occurred an annoying, somewhat scaly, red, dened and well defined involvement within forty-eight hours. The localization depended on whether the dress was short or long sleeved. In the former, the areas of the axillary folds, the sternum and the neckline of the dress showed involvement, in the latter in addition to the foregoing areas, the antecubital fossae were also affected. The degree of dermatitis was dependent on the length of time which the dress was worn. When the causative factor was not soon discovered (as in two instances), the inflammatory reaction became much more severe the skin becoming edematous later a papulopustular

eruption became superimposed. This secondary pyoderma involved the extremities and the trunk.

The treatment of this contact dermatitis is exceedingly difficult, the mere removal of the offending clothing is not enough as is the case in so many other forms of this group of dermatitis. The skin has to be kept well lubricated with such a preparation as coconut oil. I usually ask these patients to remain at home for several days, put on loose mushy garments and keep them selves literally soaked in oil.

Usually as a result of this chemical irritation there remains the earmarks of the epidermal insult for a considerable period in the form of hyperirritability of the affected skin which will appear as a dermatitis on the slightest provocation.

LESTER HOLLANDER M.D., Pittsburgh

Characteristics of various amebas

the fresh stool between the slide and cover glass. Examine with the low power and then with oil immersion.

In the stained smear the cysts are often mistaken for air bubbles by beginners. They are also to be differentiated from

Blastocystis. The addition to the mixture of iodine 1 part potassium iodide 2 parts, and water 100, or 2 per cent eosin solution, helps this examination. Eosin stains the background but does not stain the amebas and flagellates. The iodine stains nuclei brown. It is therefore very important in examination for cysts. The Dutch investigators Bayor and Kuenen use a concentration method to demonstrate cysts. Another method by Riparte and Petit in order to make the cell structure more visible is as follows: copper chloride 1 Gm, copper acetate 1 Gm, solution of formaldehyde 50 cc, camphorated

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

INADEQUATE TREATMENT OF SYPHILIS

To the Editor—A man aged 29 had a chancre about two years ago and about eighteen weeks after infection consulted a physician who gave him eight intravenous injections of nearsphenamine together with injections of mercury. Six months later he had what the physician told him was a second chancre, and at this time he received six more intravenous injections followed by twelve intramuscular injections, presumably nearsphenamine and bismuth respectively. During the course of these injections he had a rash which he was told was a secondary eruption and which finally disappeared again in the course of treatment. Following this he discontinued further treatment of his own accord and six months ago came to me for treatment with his trunk and extremities covered with a papular eruption. In the genital region where the folds of skin rub together were open sores apparently condylomata. He felt very much "run down" but did not complain of pain of any kind. I took this to be a recurrent secondary reaction for the pupils reacted sluggishly both to light and in accommodation but the neurologic examination was otherwise negative. A blood test at this time was Kolmer 4 plus, Kline 2 plus. I started him on injections of 4.5 Gm of nearsphenamine at five day intervals until six treatments had been given. A blood examination at this time revealed the Kolmer reaction to be 4 plus and the Kline reaction 4 plus. I then gave him twelve biweekly 1 cc injections of bismuth salicylate in oil containing 0.13 Gm of the drug per cubic centimeter. Blood examination then gave a Kolmer reaction of 4 plus, Kline 3 plus. After two injections of the nearsphenamine the eruption disappeared and the patient gained weight and felt better in spite of the turn of the blood picture toward the positive side. I then gave him a rest of three weeks and began a repetition of the previous treatment except that I increased the nearsphenamine to 6 Gm because the patient weighed 190 pounds (86 kg). During the course of this treatment he developed typical arciform syphilids on the lower limbs and dry fissured lesions about the fingers, the palms of the hands and some on the forearms. He states that he does not feel as well as he did during the first course. I continued with the bismuth injections up to eight and then the blood became Kolmer negative, Kline 4 plus. Should I continue treatment in the same manner and if not, what should be done? Please omit name and address.

M D Minnesota

ANSWER—The treatment of this patient, accepting the history as it is given, but correcting the misplaced decimal points in the dosage of nearsphenamine, has been inadequate throughout. The data are insufficient to determine whether the recurrent penile lesion was a bona fide reinfection or a monorecurrence. The first papular eruption with erosive lesions in the groins may well have been either delayed secondaries or secondaries associated with a reinfection. It seems more probable, however, that the whole picture is to be interpreted as serial relapse assuming increasingly the characteristics of a precocious tertiarism. There seems little doubt from the description of the treatment, including the introduction of rest intervals and the inadequate dosage of nearsphenamine and heavy metal that the patient is on the verge of the most serious complications as a result of induced allergic response to his infection following inadequate treatment. The most intensive and vigorous treatment is therefore indicated, including a shift from nearsphenamine to arsphenamine and the administration of bismuth salicylate in doses of 0.2 Gm every four to six days for several injections, followed by the institution of a five to seven day interval. Close attention must be paid to the mouth during this time. It is now a recognized fundamental principle that treatment in early syphilis should be continuous and not intermittent and no attention should be paid to the outcome of serologic tests so far as the direction of treatment is concerned during the eighteen months, or even for two years. An effort should be made to approximate at least forty injections of arsphenamine, and from a year to eighteen months with heavy metal.

EFFECTS OF EPHEDRINE IN NOSE

To the Editor—Will the frequent use of nose drops containing 1 per cent of ephedrine have any harmful effect when given to children? What harmful effects might ensue if any and what is the maximum dosage that can be used in this fashion? Please omit name. M D Kansas

ANSWER—The frequent use of nose drops containing 1 per cent of ephedrine would in most instances even over a long period not produce any condition that could not be relieved by ceasing to use the drops. From time to time patients develop a tolerance for the ephedrine so that it does not work well in the nose, and a few may develop hay fever-like symptoms in addition to their original complaints. One must guard against

the use of too much ephedrine at a time with a resultant swelling of the drug, with its constitutional reactions. In very young children, nose drops of oily character have been known to enter the lung, producing undesirable reactions. Ephedrine may be used in oily solutions in strengths of 1 per cent and in aqueous solutions in strengths of from 1 to 3 per cent.

ALCOHOLIC LIQUORS AT SPAS

To the Editor—I have often heard it stated that alcoholic liquors are dangerous if taken at a time during which a person is undergoing spa therapy, i.e., drinking a natural mineral water and taking hydrotherapy. Is there any physiologic reason for this statement? Please omit name.

M D, Indiana

ANSWER—There is a psychologic rather than a physiologic basis for this prohibition. "Spa therapy" aims at alterative effects, i.e., a change in a person's constitution as a result of change in habits, and the elimination of the use of alcoholic liquor may be of greater importance in the 'cure' than the drinking of the natural mineral water. It is just as bad for a person to drink liquor at home as at a spa.

NERVES AFFECTED IN JAKE PARALYSIS

To the Editor—I have a patient with paralysis of the hands and lower extremities (jake paralysis). Please advise me just what nerves are affected to cause this condition. D E LITTLE M D Eufaula, Okla.

ANSWER—The same nerves are not affected in all cases of so called jake paralysis. Hence the way to find out just what nerves are affected in this particular patient is to go over his motor and sensory condition carefully. The various movements should be tested and a list made of the muscles showing distinct weakness. Next the patient's sensation for touch, pain, heat and cold should be determined and the areas affected should be mapped out. By consulting books on anatomy or neurology it is easy to learn what nerves correspond to the muscles and skin areas involved.

USE OF OXYGEN TENT IN PATIENT WITH HEART DISEASE AND GLYCOSURIA

To the Editor—Please send me some information of what method and how soon to remove a patient from an oxygen tent in coronary thrombosis and hypostatic congestion of the lungs. Also if the patient had a blood sugar 333.5 urea N 28. Would you use insulin in such cases? The patient who took sick suddenly was never complaining before this illness.

LEOPOLD HARRIS M D New York City

ANSWER—There is no uniform method of removing a patient from the oxygen tent. The general practice is to keep the patient in the tent as long as there is cyanosis or distressed breathing. If one is satisfied that convalescence is established, it is wise to reduce the oxygen pressure gradually to see how the patient breathes in a reduced atmosphere.

Regarding the blood sugar, insulin would seem to be contraindicated unless there is a real diabetes present. Was there glycosuria? Had the patient a diabetic history? Was there hyperglycemia a constant finding or just a single incident? Since it is known that both insulin and hypoglycemia may be harmful to the damaged heart (Strouse, Solomon, Soskin, Samuel, Katz, L N, and Rubinfeld, S H. Treatment of Older Diabetic Patients with Cardiovascular Disease, THE JOURNAL, May 14, 1932, p 1703), it should not be used without a real indication. If a patient has true diabetes and does not react to moderate restrictions of diet, small doses of insulin might be advisable, but the patient should be watched very carefully, and the occurrence of any cardiac symptoms or signs would be a definite indication for stopping insulin therapy.

CHANGES IN KAHN TEST

To the Editor—Dec 28 1931 a white woman aged 40 consulted me. As she came into the office I noticed a definite ataxia to the right. Her chief complaints were extreme nervousness, a tendency to stagger to the right side, fainting spells in which she always fell to the right side and terrible right temporal headaches. Examination revealed hyperactive reflexes on the right side of the body. The pupils reacted evenly to light and in accommodation. There was a questionable positive Romberg sign. A tentative diagnosis of brain tumor was made and she was sent to an ophthalmologist for examination. The report came back that there were no choked disks and that there were no changes in the eyegrounds to account for the symptoms. A Kahn test was done which came back 4+. There was no history of any syphilitic infection. The woman was married ten years previously and there is no history of infection in the husband. His Kahn test was negative on two different tests. From Jan 16 to Feb 27 1932, she was given sixteen doses of 1.5 cc each of

bismuth arspenamine sulphionate intramuscularly and seven doses of metraphen consisting of 10 cc each intravenously. A specimen of blood then showed a Kahn reaction of 2+. From March 12 to June 7, 1932, she received seventeen similar doses of bismuth arspenamine sulphionate and four similar doses of metraphen. She was then changed to sodium bismuth thioglycolate and from June 11 to Oct. 8, 1932, she received twenty-four doses of 3 grains (0.2 Gm) each. Her blood at this time still showed a 2+ Kahn reaction. She was then changed to a solution of sodium bismuth iodide in ethylene glycol and from Nov. 5, 1932, to Jan. 21, 1933, she received twenty doses consisting of 2 cc each. At this time her blood showed a 4+ Kahn reaction. She was then changed to arspenamine. From Jan. 21, 1933, to the present date she has received two courses of six injections each. Each injection is spaced two weeks from the previous one. Throughout the whole time of treatment she has taken 25 grains (1.6 Gm) of potassium iodide daily. Why did this patient get a return to a 4+ Kahn reaction a year after treatment was started, in view of the fact that her Kahn reaction dropped to 2+ after only two months of treatment? Is this patient getting sufficient treatment, and if so, is it directed correctly? Is there any further treatment that you would suggest? Clinically the patient is much improved. She has no attacks or fainting spells and no more headaches. Kindly omit name.

M D, Missouri

ANSWER—The question as to why a 4+ Kahn reaction is changed to 2+ following antisyphilitic therapy cannot be answered with certainty, since the true basis of a positive serology is not as yet definitely known. It is to be remembered that there is not always a direct relation between serologic potency and clinical symptoms. A patient showing a very strong reaction might be free from clinical symptoms, while a patient showing a weak reaction might be very ill. Serologic potency, it is believed, depends on the extent of active syphilitic lesions present in the body, while clinical symptoms depend on the particular organ or organs that are being attacked by the spirochete. It is possible that, following syphilitic therapy, certain lesions might be affected more than others and produce as a result, improvement in clinical symptoms and yet at the same time an increase in serologic potency. As to the question of therapy, it cannot be adequately answered without knowing the Kahn reaction (and colloidal gold curve) on the spinal fluid, since it is possible that this patient has syphilis of the central nervous system.

TREATMENT OF SYPHILIS IN PREGNANCY

To the Editor—In a case in which the veins are exceedingly small and inaccessible would you consider it good therapy to use sulpharsphenamine intramuscularly in a pregnant woman of about four months? Is there any increased danger of exfoliated dermatitis aplastic anemia with purpura or anemia haemorrhagica occurring? Would the administration of liver extract offset to any degree the danger of the anemias mentioned? Can a close observation of blood smears and count give an early enough warning of any tendency to these diseases? Or could you suggest anything better to be given intramuscularly? Would a dosage of 0.5 Gm of sulpharsphenamine be excessive every week or should less be used? Bismuth should also be used every week should it not? Please omit name.

M D Ohio

ANSWER—The use of sulpharsphenamine intramuscularly in adults, to say nothing of pregnant women, is not recommended on account of the greatly increased danger of exfoliative dermatitis and aplastic anemia from the use of the drug. This increased risk has been amply demonstrated by the most recent studies of reaction to arsenicals used in the treatment of syphilis. There is no way of escaping this risk by any prophylactic measure, particularly as applied to the onset of agranulocytosis or aplastic anemia.

The treatment of this patient can be conducted, if necessary, exclusively with bismuth compounds or with bismuth arspenamine sulphionate in the full adult dosage. If bismuth arspenamine sulphionate is employed, an effort should be made to give it as often as twice a week for a series of forty injections. If a preparation of bismuth alone is used, one of the oil soluble bismuth compounds or bismuth salicylate could be given once a week until two weeks before the date of expected delivery.

HAIRY MOLES OF FACE

To the Editor—A boy aged 14 years is about to begin shaving. His face was always clean until his tenth year when several pigmented areas about one-eighth inch in diameter made their appearance along the sides of both face and chin. The moles show an abundant growth of hair while there is only a scanty growth of beard and mustache. Would shaving have any injurious effect on the moles? Are there any safe depilatories to be used instead of a razor? Please omit name.

M D New York

ANSWER—Moles in the bearded region of the face in young persons frequently develop coarse black hairs, which contrast with the downy growth of the rest of the face. Shaving would not have any injurious effect on the moles. Depilatories should not be used instead of a razor. If the moles at any time show

signs of irritation they should be excised or removed with electrodissection and the hairs destroyed with the electric needle.

DIAGNOSIS OF ANGINA PECTORIS AND CORONARY DISEASE

To the Editor—1. Can a man have sclerosis of the coronary arteries with attacks of angina pectoris relieved by glyceryl trinitrate and yet have a normal heart sound, pulse, blood pressure and electrocardiogram? 2. Is there any pathognomonic objective sign that will positively diagnose the condition, should the history of cardiac pain be concealed from the examiner for some reason as in insurance examinations? 3. How can one differentiate the malingerer from the actual patient complaining of anginal attacks that is, by objective signs especially when the electrocardiogram, blood pressure and sounds are negative (as in the examination of prisoners)? Please omit name.

M D New York

ANSWER—1. Angina pectoris is characterized by no objective signs. The heart may be normal on physical examination, with normal blood pressure or blood pressure either higher or lower than normal with no roentgenologic changes, and with normal electrocardiograms, and the patient may still have typical attacks, which are relieved by glyceryl trinitrate. At necropsy, no more coronary sclerosis may be found than is concomitant with the patient's age. All one can say is that for some reason the blood supply to the heart muscle is inadequate for the needs of the muscle at that time. That reason may be coronary sclerosis. There is a great deal of reason for assuming in some cases that there is a temporary vasoconstriction of the coronary arteries, but this is a matter of opinion.

2. There are no objective signs pathognomonic of angina pectoris or of coronary disease. Many cases will show electrocardiographic changes but not all. The diagnosis must be based entirely on the patient's account of the attack.

3. If the patient conceals the history, the examiner has nothing on which to base his opinion. Certain electrocardiographic changes may indicate anatomic changes in the heart, probably due to coronary disease, but they tell nothing of whether the patient has attacks of angina pectoris or not. In cases of doubt it is better to accept the patient's story. A great many patients with supposed false angina and supposed malingerers have died during a so called pseudo attack.

ITCHING OF PHARYNX AND TONGUE

To the Editor—I have recently completed a rather exhaustive allergic study on a patient suffering from allergic bronchitis and bronchial asthma. With the removal from her environment of a number of the offending allergens and a course of pollen desensitization there has been a great improvement in the symptoms. A minor degree of pathologic change in the nose and a fragment of tonsil are present. These are both being treated regularly by a competent rhinologist. The patient is severely distressed by an intractable itching of the posterior pharynx and the base of the tongue. This appears to precipitate coughing spells and is annoying both day and night. I am aware of the fact that this symptom is frequently encountered in allergic states, but in view of the marked general improvement I believe this may be a purely local condition which might be relieved by local measures. Can you suggest some therapeutic measure that would be of value? Kindly omit name.

M D New Jersey

ANSWER—Small pellets of ice placed on the posterior third of the tongue and allowed to melt there often relieve irritation in this region. Gargling with ice cold water a number of times a day is also sometimes beneficial. When these measures fail, tablets containing a small amount of orthoform or ethyl amidobenzoate may be used every two or three hours, the tablets being allowed to dissolve slowly in saliva after being placed on the tongue. Internally, the use of antipyrine in doses of from 0.13 to 0.26 Gm three times a day together with tincture of belladonna will often alleviate the irritation.

HYPOPHYSEAL CACHEXIA

To the Editor—Can you give me some references on hypophyseal cachexia? A woman aged 24 unmarried complains of loose teeth, underweight (81 pounds or 36.7 kg) and a weak voice. Her weight has remained the same for the past seven or eight years. She appears much older than the stated age there is marked loss of nutrition the voice is weak and high pitched there has been no loss of body hair although the eyebrows appear scanty. Inspection of the teeth shows no infection of the gums but a border of marked pallor extends round the gum margin about half an inch wide. Beyond this point the mucous membrane appears normal. The cusps are merely sitting on the alveolar process no root infection exists and the remaining teeth are normal roentgenographically. She has a fairly large goiter of the right lobe with no toxic signs. There is a low to and fro murmur opposite the second costal cartilage on the left. The heart is not enlarged. The fluoroscopic examination suggests a patent ductus arteriosus. The remainder of the physical examination is within normal limits. Routine

blood studies are well within normal. The Kahn reaction is negative. The urine shows no albumin or sugar and the microscopic examination shows nothing abnormal. Neurologic examination with special attention to any hypophyseal disturbance is negative. Studies of the basal metabolism and calcium studies of the blood and urine have not been done. Treatment has consisted of attempts to increase the weight by a high caloric diet. However though the patient is cooperative she cannot take even a 2000 caloric diet. A high calcium diet has been attempted in conjunction with the high caloric diet, but unfortunately I cannot overcome the vomiting of milk that promptly follows its ingestion. Might such a syndrome be considered suggestive of the so-called Simmonds' disease? Would you care to comment on the possible diagnosis and therapy if any? Please omit name. M D Michigan

ANSWER—The case seems to require more study before a definite diagnosis can be made. Certainly the basal metabolic rate should be determined and a careful gastro-intestinal study should be made. Also a careful analysis of the nervous and psychologic reactions is indicated to exclude the possibility of anorexia nervosa being the basis of the patient's inability to eat. As described the syndrome does not seem like the cachexia of Simmonds' disease, but it does not seem advisable to advise further therapy until the suggested studies are undertaken.

TYPHOID VACCINE IN ARTHRITIS

To the Editor—In using typhoid vaccine in chronic infectious arthritis what dose and interval are now believed to be most satisfactory and how long is this treatment usually continued? Please omit name.

M D, New Mexico

ANSWER—The question is divided into three parts: dosage, interval and duration of treatment.

1 The initial dose of the intravenous injection varies between 10 million and 50 million, depending on the source of vaccine. Many hospitals make up their own, and therefore the potency varies. The dosage may be increased by 25 million at each successive injection, depending on the patient's response or reaction.

2 The interval depends on the reaction. Some authorities give the injection every two days until the patient gets a chill and develops fever. Others use the plan of an interval of from four to seven days.

3 The duration of treatment varies with the individual. Some physicians establish the rule of giving a dose every two days until chill and fever appear and then they stop. Others give the injection every four to seven days until the patient has had six good reactions.

NEUROCIRCULATORY ASTHENIA AND DYSPNEA

To the Editor—In examining men for enrolment into the CCC I have not infrequently come across youths (ages 18-25) who show a marked amount of dyspnea on merely hopping up and down on one foot for a minute or two. Many, and it is in these cases that the question is asked on auscultation show no evidence of decompensation (rales in chest) and no murmurs of any type. The blood pressure was normal in the majority. There was no evidence of lung changes and no history suggestive of rheumatic infection. Urinalysis was negative. What suggestions may be offered as to the cause of the dyspnea? I now have several similar cases in my camps. Please omit name.

M D California

ANSWER—It is possible that in the absence of cardiac or pulmonary disturbances the dyspnea might be produced by anemia. Another possibility is merely poor muscular condition. If these factors are not present, a neurogenic origin must be considered. The chief syndrome to be considered under this heading is neurocirculatory asthenia. Respiratory manifestations may predominate in this condition, with the cardiac and muscular elements in the background. In fact, patients may have constant panting even while at rest quite as they may have constant palpitation or diarrhea. Other symptoms, however, should be brought out during work, namely, early exhaustion, tremor, palpitation, tachycardia and sweating.

SENSITIZATION TO ALCALIGENES ABORTUS

To the Editor—I have a patient a veterinarian who is sensitized to *Alcaligenes abortus*. If he does not wear rubber gloves when called on to treat a cow infected with that disease a severe dermatitis of his hands and arms develops. Is there any means or methods of desensitizing for this infection? Kindly omit name.

M D, Minnesota

ANSWER—If it has been demonstrated that the veterinarian is sensitized to *Alcaligenes abortus*, the simplest preventive measure would be to insist that he wear rubber gloves when he has direct contact with fresh animal tissues. It is assumed that the possibility of contact dermatitis from bovine vaginal secretions has been excluded. If not, this could be done by skin tests with bovine vaginal secretions or bovine serum, or both.

In skin testing for sensitivity to *Alcaligenes abortus* it is important to carry out the intradermal test with very dilute suspensions of the organism in order to avoid a severe reaction. The patch test, the sediment of killed organisms being used under a piece of adhesive plaster, instead of the usual intradermal test, might be a safer procedure.

If the disturbance is proved to be due to sensitization to *Alcaligenes abortus*, it would be possible to desensitize the patient by intradermal injections or by subcutaneous injections of an *Alcaligenes abortus* vaccine. It would be well to use a detoxified suspension of the organisms for the desensitization rather than the heat-killed or formaldehyde treated suspension as described by Tishay (*J Infect Dis* 51:286 [Sept-Oct] 1932). The injections should be small beginning with 0.01 cc and should be continued over a considerable period until skin tolerance to an intradermal injection of heat-killed organisms is achieved.

CINCHOPHEN POISONING

To the Editor—Please give me what information you can about cinchophen poisoning, the antidote and its relation to acute yellow atrophy of the liver. How quickly do poisoning symptoms appear? What tests are used to prove the connection of cinchophen action on the liver? How common is acute yellow atrophy of the liver due to cinchophen? Please omit name.

M D Massachusetts

ANSWER—Worster Drought was the first to describe liver disturbances in patients who had taken cinchophen. The first fatality showing yellow atrophy of the liver was reported by Cabot in 1925. Since that time about forty-nine fatalities and fifty-eight severe poisonings have been reported in the literature. It is important to know that fatal accidents may occur within a short time even with therapeutic doses as small a dose as 3 Gm daily for two days may produce severe toxic symptoms, on the other hand, 324 Gm has been taken in the course of four months before the appearance of toxic symptoms. Either the course of the poisoning is rapid with the death of the patient or it takes weeks or even months to recover from the toxic effects. From the reports in the literature it appears that hypersensitivity may play an important part in the production of cinchophen poisoning. In animals, degenerative changes of the liver have been reported only with large doses. Control of the liver function during the administration of cinchophen appears to be advisable. Gastro-intestinal disturbances and the appearance of bile pigments in the urine are the first symptoms of the poisoning. After definite symptoms have set in the treatment is usually not very effective. There is no specific antidote, occasionally encouraging results have been reported by increasing the glycogen store by a carbohydrate diet, by the injection of dextrose and insulin and by duodenal lavage with magnesium sulphate (Eimer K. *Deutsche med Wchschr* 57:1663 [Sept 25] 1931; Walker, H G. *New England J Med* 204:253 [Feb 5] 1931; Weiss C R. Toxic Cirrhosis of the Liver Due to Cinchophen Compounds, *THE JOURNAL* July 2, 1932, p 21; Grigg W K, and Jacobson, V C. *Ann Int Med* 6:1280 [April] 1933).

USE OF RESORCIN SULPHONATE IN HEMORRHOIDS

To the Editor—Please give me some information concerning the action of resorcin sulphionate with special reference to its application in rectal inflammations and hemorrhoids. Is it ever used internally, and, if so for what and why? Please omit name.

M D, Pennsylvania

ANSWER—Sulphonation greatly reduces the specific activity of the phenols, and resorcin sulphionate is probably no exception to this general proposition. If this is true, it is doubtful whether resorcin sulphionate is of any special value either locally or internally.

USE OF HEXYLRESORCINOL

To the Editor—Regarding your answer to the query in *THE JOURNAL* August 19, page 625 Sharp and Dohme inform me that hexylresorcinol is not obtainable in the form you specify for oral administration. The strongest product is the Caprokol capsule 0.15 Gm. This would require more than six capsules for a 10 year old child. The solution for use as an enema could be obtained only by buying hexylresorcinol solution S T 37 in small bottles 12 ounces I believe, being the largest. I am very anxious to try this method in a resistant case of *occurus* infection. Any suggestions would be welcome. Please omit name.

M D New York

ANSWER—The presence of a solvent, such as oil or glycerin, greatly reduces the activity of hexylresorcinol. On this account it is doubtful whether the use of Caprokol or hexylresorcinol solution S T 37 in enemas would be as successful as using crystalline hexylresorcinol.

As stated in previous publications, hexylresorcinol is controlled by Sharp and Dohme, who have temporarily withdrawn

the crystalline form from the market on account of cases of local irritation from improper administration when children have chewed up hexylresorcinol pills and obtained temporary irritation of the mouth. In the meantime, investigators are trying to find some acceptable means of administration.

RELATIONSHIP OF MUSCLE CRAMP TO DROWNING

To the Editor—When one is reported to have been drowned as a result of cramps what is thought to be the condition causing a good swimmer to drown? Please omit name.

M D Pennsylvania

ANSWER—Cramps are involuntary sustained contractions of skeletal or visceral muscle, of a tonic or tetanic character. It is well known that cramps or spasms of skeletal muscle may be induced by prolonged and intense stimulation of the cold nerve endings of the skin. Such muscular spasms may also be induced by severe physical exertion in people not in good physical training. A man may therefore be a good swimmer but not in good physical training or practice for swimming or other severe physical exertion. Such muscle cramps or spasms may involve any muscle or group of muscles in the body but usually not all of them simultaneously. This is true not only of the visceral but also of the skeletal muscles. It may involve the diaphragm and the other muscles of respiration. The cramp or muscle spasm is usually associated with local pain, which tends to inhibit use of other muscles that involve the spastic members either in motion or in tension.

It is conceivable that the trained swimmer might suffer severe spasms of some part of the gastrointestinal tract leading to such severe pain that the exertion of swimming becomes more or less intolerable. Spasms or cramps of the skeletal muscles in swimming rarely come in the hands, arms and legs at the same time. Probably the death or drowning on the part of a trained swimmer from cramp is largely the result of panic or confusion from fear. The notion that cramp on the part of a swimmer is so dangerous and fatal is generally believed and hence when he feels such a cramp locally he begins to be confused and executes all kinds of useless and futile movements which accentuate or extend the spasm. It is well known that good swimmers who have some understanding of the body machine can handle themselves well in water with cramps of the arms or cramps in the legs merely by turning on the back and keeping afloat by a slight movement of the arms and legs not already involved in the cramp. Such resting in the absence of fear usually permits the spasm to subside and the swimmer can go on.

REFLECTION OF LIGHT FROM EYES OF ANIMALS

To the Editor—Why do the eyes of some animals reflect light in darkness and other animals' eyes do not? Which of the commoner animals in this country belong to each group? Please omit name.

M D Pennsylvania

ANSWER—The visibility of light reflected from any eye is a factor of the intensity of the source of light, the diameter of the pupil, the angle of the incident and reflected beam and the color of the reflecting fundus. In addition to these factors, there must come into consideration the relative intensity of the illuminating beam and of the area round about the animal. The two factors that are mainly responsible for the visibility of reflection from the eyes of some animals and not others are the diameter of the pupil of the animal's eye and the color of the animal's fundus. With a contracted pupil, the angle of the incident and the reflected beam is so small that any slight variation from a given position prohibits observation of the reflected beam. In the majority of domestic animals, the fundus range from red to yellow and green. With such fundus colors, brilliant reflections may be expected under proper conditions such as are seen from the eyes of cats and dogs. In certain other animals, as the hedgehog and the squirrel, the fundus presents a light gray appearance and as a result no distinct reflection is to be anticipated.

TREATMENT OF HOOKWORM DISEASE

To the Editor—In THE JOURNAL Nov 25 1933 page 1746 appears a statement relative to the treatment of hookworm disease. I believe that tetrachlorethylene is in all probability as effective as carbon tetrachloride and theoretically decidedly preferable because it does not cause liver damage or any other intoxication that I could discover. Clinically it seems to be as effective as carbon tetrachloride. Like any anesthetic when taken by mouth it may cause temporary giddiness which should not be considered intoxication. The only contraindication that I know against its use is in cases of mixed infestations in which both Ascaris and hookworm are present in which condition it may cause migration of Ascaris with complications.

Hawaii October Examination

Dr James A Morgan secretary, Board of Medical Examiners reports the oral and written examination held in Honolulu Oct 9-12 1933. The examination covered 10 subjects and included 55 questions. An average of 75 per cent was required to pass. Seven candidates were examined, 5 of whom passed and 2 failed. The following schools were represented:

School	PASSED	Year	Per
		Grad	Cent
Northwestern University Medical School	(1933)		85.4
Tulane University of Louisiana School of Medicine	(1933)		86.5
Jefferson Medical College of Philadelphia	(1934)		83.5
Vanderbilt University School of Medicine	(1930)		84
University of Wisconsin Medical School	(1932)		84.7
School	FAILED	Year	Per
		Grad	Cent
Chicago Medical School	(1920)		70.7
St Louis University School of Medicine	(1932)		70.4

Two physicians were licensed by endorsement during September. The following school was represented:

Book Notices

The Law Against Abortion Its Perniciousness Demonstrated and Its Repeal Demanded. By William J. Robinson M.D. Consultant to the Bronx Hospital. Cloth Price \$2. Pp 123. New York: Eugenes Publishing Company Inc. 1933.

Abortion Legal or Illegal? By A. J. Rongy M.D. F.A.C.S. Cloth Price \$2. Pp 212. New York: Vanguard Press. 1933.

These books are omens of an expansion in the United States of the demand for sex freedom. So far has the religious taboo against abortion sunk into the consciousness of Western man," says Rongy, "that today even the liberal advocate of birth control does not carry his reasoning to its logical conclusion in the support of abortion." And, says Robinson, now that the prevenception battle has been won, we are permitted to go a step further and devote some of our energy to the subject of necessary abortion." Both books must be recognized as propaganda in support of a movement to bring about the relaxation or even the repeal of present laws relating to the inducing of abortion. Neither author attempts to show the good that has been and is being accomplished by the laws now in force or the evils that may follow in the wake of their repeal or relaxation. The attitude of both is well shown by Robinson's statement:

The law against abortion should be repealed first because it is a vicious injurious law and second because it is a futile unworkable law. And *en passant* if the law were one hundred per cent workable and efficient if it made the performance of abortions really impossible it would be the most pernicious law in our penal code because it would lead to an enormous number of suicides to an incalculable amount of anguish shame disgrace and ostracism.

The format of Robinson's book and the general tone of its contents leave one in doubt whether it is intended for the medical or the lay reader. Of 100 pages of text, forty are devoted to heart-throb stories of women who suffered, and some of whom died, as the result of criminal abortions or because of inability to have abortions induced. Eighteen pages are devoted to a discussion of methods for inducing abortion, a discussion too elementary for the medical profession and yet of sinister possibilities so far as the public is concerned. The medical profession hardly needs instruction concerning the differences between emmenagogues abortifacients and ecboolics. To tell the lay reader that in a pregnancy of but a few days' duration emmenagogues 'may also help and then to devote five pages to a discussion of The Best Emmenagogue Combinations,' giving two prescriptions for such combinations, certainly suggests and makes convenient the lay prescribing and use of such drugs. Robinson lays down a brave thesis which he himself seems afraid to follow to a logical conclusion.

For the one thousandth and first time we shall repeat and we shall repeat it again and again that we want life but only such life as is desirable to its possessor and to those around. Such life is desirable

and sacred. But life that is a curse to its possessor and which he goes on living merely out of cowardice, a life of pain a life of disease, a life of shame, a life of endless poverty struggle and drudgery, a life of misery to its possessor and to those around him and to the race in general is not desirable and is not sacred. And to prevent such life is the highest service that a man can render to the individual family, to the community and to the human race as a whole!

Here we have Robinson the realist. His thesis clearly justifies the killing not only of the embryo and fetus but also of all human beings who come within the category the author defines. It justifies infanticide. It justifies suicide. It justifies euthanasia either with or without the consent of the person whose life is to be destroyed. But Robinson the idealist will have none of this. He writes:

I do not see eye to eye with some of our ultra radicals who consider abortion a matter of no importance (I mean ethically not hygienically) and who would permit the artificial emptying of the uterus at any time—even as late as the seventh or eighth month—some go further and would not recoil even from an early infanticide. I do not wish to be considered an apostle or adherent of that sort of ultra radicalism.

Robinson demands however, neither more nor less than the complete and total abrogation of any law against abortion, and only if complete abrogation is impossible is he willing to accept even a very radical modification of the law. He sums up his demand as follows:

And so because the law against abortion accomplishes no good but causes an incalculable amount of harm it should be repealed.

If desired a clause could be inserted permitting abortion only until the end of the third month and only a certain number of times in the case of any given woman as is the case now in soviet Russia.

But if the induction of abortion is to be tolerated "in order to do away with infanticide, in order to save thousands of women from the hands of incompetent and ignorant bunglers, in order to save thousands and thousands of women from shame, disgrace ostracism, blood poisoning, invalidism, death and suicide" why tolerate it only during the first three months of pregnancy? And if this limitation is proposed because of the increased danger to the mother after the three-month deadline, that very danger, it is obvious, is a reason for enabling women who desire abortions after the third month to obtain the services of the most skilled physicians, not a reason for driving them to the underworld and to incompetent and ignorant bunglers. The suggested limitation of the number of induced abortions any given woman may have is obviously impracticable, for physicians whose services might be sought for such operations would have no means other than the word of interested applicants for treatment to inform them whether those applicants had or had not been subjected to their respective allotted number of operations.

Rongy's book contains about 200 pages of text. For a book of its size and pretensions an index seems necessary, but none is provided. Rongy writes more directly to the medical profession than does Robinson, but even so it is somewhat difficult to determine whether his book was written for the profession or for the public. About one third of it is devoted to a discussion of the historical background of abortion and of the religious attitude toward it. Here and elsewhere in the book the intelligent reader will feel keenly the lack of documentation. It may be true for instance, as the author states, that in the Oath of Hippocrates the pledge concerning the induction of abortions is not based on ethical, religious or professional grounds but originated somewhat in the nature of a guild or trade union rule, to prevent physicians from encroaching on a field already occupied by 'the female doctors of Greece, who were experts in abortion,' but the serious reader would like to know the authority for this hypothesis. Likewise, when the reader is told that the national total of abortions has been estimated to top 2,000,000 per year, and that "it is the opinion of competent medical observers during the last thirty years that there are more criminal abortions performed in this country than in any other country in the world," he would like to be given some basis on which to determine how seriously to regard those statements.

Notwithstanding Rongy's advocacy of the utmost freedom with respect to the inducing of abortion, he calls attention to the fact that abortion threatened the stability of the Roman Empire so gravely that the poets historians and philosophers of that day sought means for stopping it and persuaded the legislators to enact restrictive legislation. With what safeguards, then, does he propose to surround the induction of

abortion under his suggested scheme in order that our own national stability may not be jeopardized? What he proposes is apparently the unrestricted induction of abortion when desired by a pregnant woman, in any case of illegitimate pregnancy and in the case of any woman who is mentally defective whether married or single, or who has been deserted by her husband or left a widow while pregnant, or who has had several children and who wants to halt further child bearing, in order to preserve her health, or whose husband is already providing for several children but is unable to provide economically for another child. Whether Rongy proposes the establishment of official machinery for determining before an abortion is induced whether the applicant is or is not entitled to the operation, he does not say.

Rongy is particularly bitter toward the church because of its condemnation of abortion. He apparently overlooks the fact that human life is a continuous process, from the moment of conception to the last heart beat—gamete embryo fetus, infant child youth and man. The church condemns the killing of the human being at any time. Rongy, however, would have the government approve the killing of the gamete the embryo and the fetus. Why he would tolerate feticide and forbid infanticide and other forms of homicide is not apparent. The new-born infant may be as much of an embarrassment to its mother as is the unborn babe, the incurable invalid and the insane may be a burden, socially and financially as insupportable as is an illegitimate or an unwanted infant and in many cases the bearer of the burden of a disgraced or invalid life may himself vastly prefer that it be terminated. How is the legalization of feticide to be justified while homicide and suicide under analogous conditions are still forbidden?

Neither Robinson's book nor Rongy's would in itself justify a review of the length here devoted to it. The subject matter of these volumes, however, abortion, fully justifies it. The intimate relation that the medical profession has to the matter and the agitation that is going on for a repeal or relaxation of the law relating to the inducing of abortion require the constant earnest, thoughtful consideration of the matter by every physician. It is not for the medical profession to propose legislation in this field. Laws forbidding the inducing of abortion have not interfered, so far as is known with the inducing of a therapeutic abortion to save the life of any woman whose life has been endangered by pregnancy, nor are they likely to do so. This is true even though some such laws contain no specific provision authorizing therapeutic abortions. But the profession must watch such legislation as is proposed and endeavor to have such laws as may be enacted limited to such logical bounds as the circumstances may indicate.

Pp. 173 288 with 31 illustrations. Lieferung 5. Band III. Durch Spirochäten und Protozoen bedingte Hautkrankheiten. Von Prof. Dr. Leo Kumer. Durch unbekannte Erreger bedingte Hautkrankheiten. Von Prof. Dr. Leo Kumer. Paper Price 8 marks. Pp. 289 448 with 68 illustrations. Lieferung 6. Band IV. Wesen und Verlauf der Frühsyphilis im Einzelnen. Von Prof. Dr. Heinrich Löhe. Maligne Syphilis. Von Prof. Dr. Franz G. M. Witz. Haut und Schleimhäute bei Syphilis (einschliesslich Mund und Rachen). Lymphgefässe und Lymphknoten. Von Prof. Dr. Walther Schönfeld. Paper Price 10 marks. Pp. 165 348 with 137 illustrations. Lieferung 7. Band I. Anatomie und Histologie der Haut. Von Prof. Dr. Eduard Pernkopf und Prof. Dr. Viktor Patzelt. Paper Price 9 marks. Pp. 140 with 57 illustrations. Berlin & Vienna. Urban & Schwarzenberg. 1933.

The purpose of this publication is to give the practitioner and specialist a more compact, less detailed and more economical work of reference than was provided by the monumental

Handbuch der Haut- und Geschlechtskrankheiten which appeared several years ago. The entire work is to be delivered in twenty-five instalments which are not to be sold separately and eventually will comprise five volumes. A perusal of the first seven instalments indicates that each one is more or less monographic in character and deals with separate phases of the subject. Section 1, by Fuhs of Vienna, is a particularly valuable presentation of the parasitic skin diseases and emphasizes the recent immunologic and clinical advances made in the mycoses. The inclusion of pityriasis rosea in this volume would lead one to infer that the author feels that this eventually will be found to be mycotic in origin. The second instalment includes authoritative articles by Stühmer on general syphilis, diagnostic methods by Schönfeld, and the histology of syphilis by Frieboes. The third section is devoted to gonorrhea in its various manifestations and is along traditional lines. Section 4 by Mucha and Matras, deals with the pyodermites. In the fifth instalment Kumer has some interesting chapters on skin diseases produced by spirochetes and protozoa and those of unknown etiology, among which are herpes zoster, varicella, erythema multiforme and pemphigus. It is instructive to note the large number of new remedies that have been tried out in various German clinics in the treatment of pemphigus. In the sixth instalment the contribution by Löhe on early syphilis is noteworthy for the large number of excellent illustrations. The short chapter on malignant syphilis by Witz seems unnecessary in the light of modern chemotherapeutic success in the treatment of this disease. Schönfeld has contributed a good account of late syphilis of the skin and mucous membranes. The seventh section, by two less well known writers, Pernkopf and Patzelt, on the anatomy and histology of the skin has some interesting schematic charts and photomicrographs. If future instalments come up to the high standard of the present series there is no doubt that this work will prove a valuable and authoritative contribution, at least as compared with the average textbook. The format is excellent and the numerous illustrations, some of them in colors, drawn from some of the largest dermatologic clinics in the world, will be of great value to the student.

The Dog's Medical Dictionary. An Encyclopaedia of the Diseases, Their Diagnosis and Treatment, Poisons and Their Antidotes, and the Physical Development of the Dog. By Alfred J. Sewell. M.R.C.V.S. New edition revised by Frederick W. Cousins. M.R.C.V.S. Canine Surgeon by Appointment to H. M. King George V and H. R. H. the Prince of Wales. Cloth Price \$2.75. Pp. 324 with illustrations. New York. Charles Scribner's Sons. 1933.

As the title implies, the various items concerning practical dog anatomy, disease and treatment appear in alphabetical order. Interspersed throughout the book are a great number of pictures of various pedigreed types of dogs, such as Afghan hound, wire haired Dachshund, and Keeshond. Because of the former inclusion the book will be welcomed by every experimental laboratory. Of particular value are the descriptions with illustrations of the various types of bandages best fitted for different parts of the dog's frame. From the American point of view it is hard to understand why ether instead of chloroform is only casually mentioned as an anesthetic agent and that the Laidlaw-Dunkin method of the control of distemper is not mentioned at all.

Obstetrical Nursing. A Text Book on the Nursing Care of the Expectant Mother, the Woman in Labor, the Young Mother and Her Baby. By Carolyn Conant van Blarcom. R.N. Third edition revised with the assistance of Calvina MacDonald, R.N. and others. Cloth Price \$3. Pp. 661 with 263 illustrations. New York. The Macmillan Company. 1933.

This edition was prepared with the object of revision in two definite trends, the first, for simplification of care especially of maternity service in the home, the second, in the field of social service with especial attention to the benefits of mental hygiene in the nursing care of maternity patients. Both the text and the illustrations have been augmented with profit. The book contains all that an obstetric nurse needs to know in the care of her patients and is an excellent reference work for the student and the graduate nurse. The teaching is sound and the text clear and direct. The book is well put up and is printed on high grade paper and in large type. The glossary will be found indeed useful.

Medicolegal

Right of Court to Order Operation Performed on Infant—Helen Vasko, 2 years old, had a glomus of the retina of her left eye. Medical authorities of the Grasslands Hospital of the Department of Hospitals recommended that the eye be removed. Her parents refused to permit the operation and the Westchester County Society for the Prevention of Cruelty to Children instituted a proceeding in the children's court, Westchester County, New York, to have her declared a neglected child under the provisions of the New York Children's Court Act (Laws 1930, chapter 393). That act defines a "neglected child" as including one whose parent, guardian, or custodian neglects, or refuses, when able to do so, to provide necessary medical, surgical, institutional or hospital care for the child. It authorizes the children's court to provide the necessary medical or surgical care for such a child. In this case, a physician appointed by the children's court to examine the child reported that the eye was permanently blind and that the growth was probably of a malignant nature, would increase in size until it filled the eyeball, and would then burst through and protrude between the lids and that in all probability, if left to nature, it would follow the optic nerve into the brain and that the child would die. In the opinion of this physician, the child had an excellent chance of living if operated on. The court then ordered the operation to be performed and the parents appealed to the supreme court, appellate division, second department, New York.

The law, said the supreme court, is not only zealous in the protection of the civil rights of infants but has a special regard for their moral care, training and guidance. Its beneficence extends also to the conservation of their health and their physical well being, as well as the preservation of their lives. If parents or guardians neglect their duty in respect to any one of these obligations, the state may intervene. Children come into the world helpless, subject to all the ills to which flesh is heir. They are entitled to the benefit of all laws enacted for their protection—whether affecting their property, their personal rights or their persons. The Children's Court Act is constitutional, and the children's court acted in this case not only in strict compliance with the act, but with scrupulous care and moderation and on ample and competent evidence. The order of the children's court was therefore affirmed.—*In re Vasko (N Y)*, 263 N Y S 552.

Agreement in Restraint of Professional Practice Valid if Reasonable—The plaintiff and the defendant, two physicians, entered into a partnership agreement for the practice of medicine and surgery in Chicago. Under the contract, the plaintiff obligated himself not to engage in the practice of medicine, in Chicago, independently of the defendant. In a suit to enforce the payment of certain sums provided for in the contract, allegedly due from the defendant to the plaintiff, the defendant contended that the contract was against public policy because it restrained the plaintiff from practicing his profession. This restriction on the plaintiff was unreasonable, it was contended, for two reasons: first, because it was unlimited in time, and, second, because it was not sufficiently limited as to space or territory. With these contentions the Supreme Court of Illinois could not agree. In *Linn v Sigsbee* 67 Ill 75, a practicing physician sold his medical practice and obligated himself 'not to establish nor to attempt to establish a medical practice within the aforesaid township of Chili, nor within six miles of his present residence'. In that case the Supreme Court of Illinois held that an agreement to practice medicine, if reasonably limited and supported by consideration is not invalid and that the question of the reasonableness of the contract is to be determined by the court. The restraint imposed by the contract then under consideration was held to be reasonable and the contract to be valid. In *Ryan v Hamilton* 205 Ill 191, 68 N E 781, the Supreme Court reached a similar conclusion when it held valid an agreement made by a physician never again to practice medicine in or within 8 miles of a designated city without the consent of the second party to the contract,

another physician. The decision in *Linn v Sigsbee*, supra, is authority, said the Supreme Court in the present case, for the proposition that the limitation is not unreasonable because it may extend throughout the lifetime of the plaintiff. Counsel for the defendant cited no case where a restriction on the right of a person to engage in his profession, trade or business, limited to a city, town, or territory less than the whole state, has been held unreasonable on such ground. Under the contract the plaintiff was not restrained from practicing his profession at any place in the state outside Chicago and, with respect to practice in the city, the restraint was not total but only that the plaintiff would not practice his profession independently of the defendant. The contract, concluded the court, was supported by a valuable consideration, the restraint imposed was limited or partial and was not greater than was reasonably necessary to protect the contract rights of the defendant. It was not against public policy. The validity of the contract was therefore upheld.—*Storer v Brock (Ill)*, 184 N E 868.

Malpractice Injuries Attributed to Plaster-of-Paris Impression of Auricle and Auditory Canal—Dr Padden attempted to make a wax impression of the auricle and auditory canal of the plaintiff's ears so that phonettes could be made for his use while operating an airplane. According to Dr Padden, he cleansed and lubricated the plaintiff's right ear, picked it with cotton from the eardrum outwardly about a quarter of an inch, and poured in a plaster-of-paris preparation of the consistency of whipping cream, permitting the preparation to harden for eight minutes, to the consistency of hard butter. When he attempted to remove the hardened preparation a portion of it broke off and remained tightly wedged in the auditory canal. A surgical operation, performed by Dr Belknap, was necessary to remove it. Subsequently, the plaintiff lost his hearing in his right ear, the sight of his right eye, and his sense of balance, and suffered a partial permanent paralysis of the right side of his face. He brought suit against Dr Padden and Dr Belknap. Judgment was entered against Dr Padden only, who appealed to the Supreme Court of Oregon.

The real question in this case, said the Supreme Court of Oregon, is whether or not the plaster-of-paris mixture was poured down past the false isthmus into the osseous part of the plaintiff's auditory canal. If it was, Dr Padden was negligent. All expert witnesses testifying at the trial agreed that it would be proper practice to make an impression of the auditory canal with the material and by the method used by Dr Padden, if the canal was plugged up with cotton as far as the false isthmus, and if the plaster-of-paris mixture was not permitted to go deeper into the canal than the false isthmus. This, continued the court, is not a case in which a physician performs an operation to cure or remove a cause of disease. In such a case the physician is not held to guarantee results. If he possesses and uses the ordinary measure of skill possessed and used by physicians in the community and locality in which he practices, he is not liable for any damage arising from an error in judgment. In such a case, a physician can make only a limited examination of the part to be operated on. Here, there was no reason why Dr Padden should not have discovered all about the mechanical structure of the plaintiff's ear before he attempted to take an impression. All the experts agreed that no two ears are exact duplicates. The length of the canal varies. The outer or cartilaginous portion may be long and the osseous part short, or vice versa. The angle formed at the point where the outer part joins the inner part varies in different ears. It does not require an expert to know that, if a substance like plaster of paris is poured into a tubular canal that is not straight, somewhat constricted midway, and the walls of which are immovable beyond the constriction, and permitted to set until it reaches the consistency of hard butter, it cannot be extracted without breaking.

The defendant contended that there was no medical testimony from which the jury was justified in finding that he was guilty of negligence. But, said the court, the evidence showed, in conformity with standard authorities, that the auditory canal in the average person is about one inch in length and that the false isthmus is about two thirds inch from the eardrum. The

evidence showed that the auditory canal in the plaintiff's ear is about average. Dr. Padden testified that he picked the plaintiff's ear with cotton about one fourth inch outwardly from the eardrum and that he poured the plaster of paris to within that distance of the eardrum, and that it was necessary to pour it down into the osseous canal and to let it stand or harden before attempting to remove it. Thus from a purely mathematical calculation it will be observed that the material would be poured past the false isthmus. The operation was really more of a mechanical than a surgical one. In such instances, it is not always necessary to establish the allegation of negligence by medical testimony. It was a question said the Supreme Court, for the jury to determine from the facts and circumstances whether the plaster-of-paris mixture was poured past the false isthmus. If it was, there was medical testimony to support the allegations of negligence. The judgment in favor of the plaintiff against Dr. Padden was accordingly affirmed.—*Keadle v Padden (Ore)*, 20 P (2d) 403

Malpractice Limitation of Actions, Medical Books Used to Cross-Examine Witness—The plaintiff Nov. 30 1926, broke both bones of his left leg about 8 inches above the ankle. He was treated for a period of ten weeks by a physician and then employed the defendant physician, Feb. 3, 1927. A roentgen examination at that time disclosed that the bones were not in apposition. The defendant operated, joined the bones sutured them and encased the leg in a plaster cast. At the time of the trial, the plaintiff's leg was bowed backward. Alleging a faulty union of the large bone to the defendant's negligent treatment, the plaintiff sued, Nov. 15, 1929. The trial court gave judgment for the plaintiff, and the defendant appealed to the Supreme Court of Michigan contending, among other things, that the statute of limitations had run against the suit, in that it had not been instituted within two years from the time the cause of action accrued.

The statute of limitations had not run, said the Supreme Court of Michigan. While more than two years had elapsed from the date the defendant assumed charge of the case, there was evidence that as late as February, 1929, the defendant had bandaged the leg. Until treatment of the fracture ceased, said the court, the relation of physician and patient continued, and the statute of limitations had not run. Error was alleged in a ruling of the trial court that when a physician witness states that a certain book is a standard medical work, the physician may then be asked whether or not that standard work does not contain a certain statement. This is not the rule said the Supreme Court of Michigan. If a medical witness refers to a textbook as his authority, then the book referred to may be used to contradict him. The trial court erred, too, continued the Supreme Court, in permitting a medical witness, in answer to a hypothetical question, to state what in his opinion was the proximate cause of the bow in the plaintiff's leg. This invaded the province of the jury. As far as the witness could go was to state that the alleged malpractice of the defendant might cause the bow in the leg. The trial court refused to instruct the jury that an expert witness, in answering a hypothetical question, assumes as true every fact asserted in the question and that if the jury finds the asserted facts untrue, then it must disregard the answer of the expert to the question. This offered instruction correctly states the law, said the court, and should have been given. For these errors committed by the trial court, the judgment for the plaintiff was reversed and a new trial ordered. *De Haan v Winter (Mich)*, 241 N W 923. The case was tried a second time. Again the trial court gave judgment for the plaintiff, and the defendant appealed to the Supreme Court of Michigan. The trial court permitted counsel for the plaintiff in cross-examining one of defendant's expert medical witnesses to bring out the fact that the witness and the defendant belonged to the state medical society, and that a part of the annual dues of the witness was set aside as a defense fund, for the defense of malpractice suits instituted against members. Permitting the cross-examination was not error, said the Supreme Court. For the purpose of affecting the credibility of a witness he may be cross-examined as to his interest in the suit, including contribution to the expense of it. Counsel for the plaintiff sought repeatedly to have an expert witness for the defendant

name some book, publication or medical journal as entering into or forming the basis of his opinion, but the witness refused to do so. Thus baffled, counsel for the plaintiff by a series of questions sought to create the impression that the opinion of the witness was not in accord with eminent medical authority. While the trial court sustained objections to these questions said the Supreme Court, the jury must have been influenced by this method of cross examination and the defendant's case was prejudiced thereby. It constituted reversible error and the decision of the trial court was reversed and a new trial granted.—*De Haan v Winter (Mich)* 247 N W 151

Malpractice When Married Woman May Not Sue on Implied Contract—Generally a patient injured by the failure of a physician to use reasonable skill and care may sue in tort for the injury or in contract for a breach of the terms of employment. *Stokis v Wright*, 20 Ga App 325, 93 S E 27. The plaintiff in this case, however was a married woman living with her husband. She broke her leg. Attributing the necessity for its amputation to a default on the part of the defendant-physicians, she entered suit against them. Apparently because an action in tort was already barred by the statute of limitations she charged them with a breach of an implied contract to set and treat the leg with reasonable care and skill. The trial court dismissed the case, and the patient appealed to the court of appeals of Georgia Division No 2. There was no express contract by the wife to pay the physicians for their services said the court of appeals, and an implied obligation arose that her husband would pay them. Even though the patient earned her own living and her husband had consented that she should have her earnings he still had the duty of furnishing his wife with medical attention. In the absence of an express contract on the part of the wife to pay for such attention and in the absence also of facts showing clearly an assumption of individual liability by her exclusive of the liability of her husband the husband remained primarily liable. The implied contract in this case was between the physicians and the patient's husband. A suit for a breach of such a contract cannot be maintained by the wife. The trial court properly dismissed the case brought by the wife.—*Scott v Simpson (Ga)*, 167 S E 920

Privileged Communications Examining Physician Not Within Rule—An Iowa statute provides that no practicing physician shall be permitted in giving testimony, to disclose any confidential communications properly entrusted to him in his professional capacity and necessary and proper to enable him to discharge the functions of his duty toward his patient. Under this statute, said the Supreme Court of Iowa, the question of whether or not a physician may testify depends on whether or not the relation of physician and patient exists. If the relation ship does exist, the physician may not testify. If the relation ship does not exist, then the testimony of the physician is admissible. In the present case, the witness was a physician appointed by the United States government for examining veterans seeking pensions. He was directed by the government to examine an applicant for the purpose of ascertaining whether the applicant was entitled to a pension. There was no examination made for the purpose of treatment. Since, said the court, the relationship of physician and patient did not exist at the time the examination was made the testimony of the physician was admissible.—*City of Cherokee v Aetna Life Ins Co of Hartford, Conn (Iowa)* 247 N W 495

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Saccular Cardiac Aneurysm with Spontaneous Rupture

—Hunter and Benson describe an almost unparalleled type of cardiac aneurysm situated over the external aspect of the left ventricle. Death was the result of spontaneous rupture of the thin fibrous wall of the aneurysm and the pericardial adhesions about it. The mechanism by which the aneurysm was produced is not easily explained. The clinical data suggest that, three months prior to death when the patient was seen by a physician, he was suffering from cardiac symptoms referable to the heart and compatible with coronary thrombosis. The other significant observation at this time was the systolic blood pressure of 160 recorded during the seizure. Cardiac hypertrophy (640 Gm) was observed at necropsy without demonstrable cause other than possibly pericardial adhesions and the characteristic renal arteriolar lesions of essential hypertension. The authors believe that slow and progressive ischemia of a small area of myocardium brought about by high grade atherosclerosis of the vessel supplying the myocardial scar may have led to disappearance of patches of heart muscle and finally to replacement fibrosis. Less probably the scar may represent the end result of focal rheumatic or syphilitic myocarditis. Proof of these diseases is lacking, but certain features about the perivascular aortic and coronary arterial lesions are suggestive of rheumatic myocarditis. The aneurysm may have had its inception three months prior to death either during or shortly after an attack of severe thoracic pain and cardiac embarrassment.

Actinobacillosis in Man—Beaver and Thompson present a case of actinobacillosis in man in which pathologic studies were made of the lesions. The lesions are essentially similar to those that have been described in cattle, except that in man the lesions are much more widespread and sulphur granules, such as occur in bovine lesions, apparently do not occur. The authors describe the lesions in their case as granulomatous abscesses severely affecting the lungs, liver and spleen. Lesions similar to those observed in man and cattle were produced in experimental animals. The organism isolated revealed a close cultural and antigenic relation to *Actinobacillus lignieresii* and a more distant relation to *Pfeifferella mallei* and *Bacillus whitmorei*. Thompson has previously shown that *Actinobacillus lignieresii* of bovine and human origin, *Pfeifferella mallei* and *Bacillus whitmorei* are antigenically interrelated, and has proposed that they be included in a common genus. This relationship, as far as the organism in the authors' case is concerned, is also confirmed from the pathologic point of view, for the lesions in man and in experimental animals were similar to glanders as well as exhibiting similarities to bovine actinobacillosis. Although the organism under consideration showed minor cultural differences and somewhat different antigenic phenomena from a typical strain of *Actinobacillus lignieresii* of bovine origin, nevertheless, it seems justifiable to regard the organism in this case as a variant of the usual bovine strain of *Actinobacillus lignieresii*.

Brucella Infection and Immunity in Man—The method of Huddleson and his associates for determining the opsonocytaphagic power of blood for *Alcaligenes* is a modification of the Leishman and Veitch technique. The authors' studies show that the *in vitro* activity of the polymorphonuclear cells in whole citrate blood for *Alcaligenes* is an expression of immunity to *Alcaligenes* and an indication of the progress toward recovery in active infection. The absence of or a low phagocytic activity obtained in conjunction with a negative allergic skin test is evidence of susceptibility to *Alcaligenes* infection. Infection in an individual is indicated by a positive allergic skin test obtained with *Alcaligenes* nucleoprotein in conjunction with a negative or a low opsonocytaphagic activity of the whole citrated blood for *Alcaligenes*.

"Brucellin" in Treatment of Undulant Fever—Huddleson and Johnson report twelve of their eighty cases of undulant fever and the results obtained from their treatment with

"Brucellin" They prepare this agent by growing each of the three species of Alcaligenes in separate flasks of beef liver infusion broth, adjusted to a pH of 6.6, for sixty days at 37 C. The inoculated flasks are shaken vigorously at weekly intervals. At the end of the growing period each flask is examined bacteriologically and, if found contaminated is discarded. The broth is clarified by centrifugation at a speed of 3,000 revolutions per minute for four hours. The clear liquid is decanted and adjusted to a pH of 7 with tenth normal hydrochloric acid. The product from each of the three species is pooled and filtered twice through sterile Berkefeld N filters. The filtered liquid is transferred to sterile flasks or tubes and incubated for five days at 37 C to determine sterility. It is standardized and transferred to sterile 1 cc vials or stored in larger containers until ready for use. The procedure which the authors recommend for Brucellin in the treatment of undulant fever is as follows. An intradermal injection of about 0.05 to 0.1 cc of Brucellin is given to determine the sensitiveness of the patient. If no marked systemic reaction is elicited within forty-eight hours, 1 cc may be given intramuscularly. This dose should be repeated at intervals of three days until four injections have been given. The intramuscular injections usually cause a local reaction and the temperature of the patient rises to 104 or 105 F. About one to three hours after the temperature reaches its highest point, it drops gradually or rapidly to near normal. There is as a rule an increase in the severity of the symptoms which do not persist for more than twenty-four hours. If the systemic reaction from the intradermal injection is severe it is advisable to start the intramuscular injections with 0.1 or 0.2 cc. In children the beginning dose should be 0.2 cc. The ambulatory or chronic type of case of long standing does not respond readily to four injections of 1 cc of Brucellin. It may be necessary to increase the dose gradually to 5 cc by 1 cc steps in order to effect recovery in these patients. The authors are convinced that the remarkable results that they obtained in their series cannot be attributed to mere coincidence.

Alimentary Galactosuria in Diagnosis of Jaundice—

Tumen and Piersol used the galactose tolerance test in studying fifty-four cases of jaundice. Eighteen were obstructive jaundice, twenty-three catarrhal jaundice and thirteen toxic hepatitis. Galactosuria of 3 Gm or more occurred in 54 per cent of the patients having toxic hepatitis, in 78.3 per cent of those having catarrhal jaundice and in 55 per cent of those having jaundice due to obstruction. Of the group having obstructive jaundice only one patient showed a definitely positive response to the test. This patient had a stricture of the common bile duct with jaundice of a duration of four weeks. At operation, definite biliary cirrhosis was found. Two other patients with biliary cirrhosis excreted normal amounts of the sugar. Two patients with obstructive jaundice had galactosuria of between 2 and 3 Gm. In both patients the duration of the jaundice was short and nothing was found other than the slight increase in excretion of the sugar to indicate that damage of the cells of the liver existed. In one patient who had a partial obstruction of the common duct for about four months, the galactose tolerance

test was normal. Of the twenty-three patients having catarrhal jaundice, only five excreted less than 3 Gm of galactose and of these one patient passed 2005 Gm. The other eighteen had galactosuria of more than 3 Gm. Seven of the thirteen patients suffering from toxic hepatitis excreted more than 3 Gm of the sugar, and three of the remaining six passed between 2 and 3 Gm of galactose.

Treatment of Pernicious Anemia—Richter and his associates treated twenty one patients having pernicious anemia and induced complete blood remissions in three by the intravenous administration of the equine liver extract. From 2 to 4 cc (1 cc prepared from 10 Gm of liver) of the material was injected at intervals of from one to three days. Following the rapid injection of liver extract in one patient having a low blood count with an initial hemoglobin of 24 per cent and a red cell count of 840,000, a mild systemic reaction was occasionally noted. This consisted of an immediate drop in blood pressure, accompanied by a rapid, weak pulse and dyspnea and later followed by a generalized feeling of warmth. This systemic reaction was usually absent when the liver extract was injected slowly, i.e., less than 1 cc per minute. No serious reactions were observed among sixty intravenous injections. One of the three patients, previously resistant to treatment with large amounts of oral liver extract and whole liver, made a complete hematologic remission in fifty seven days on intravenous injections of equine liver extract. Equally good responses were obtained from subcutaneous and intravenous injections. Twenty-four patients suffering from relapses were treated with daily injections of subcutaneous horse liver extract. The average dose used was 25 cc, containing the active principle of 25 Gm of horse liver. Patients entering the hospital in a semicomatose or moribund condition received two or three injections (from 50 to 75 Gm) daily until evidence of a reticulocyte response was obtained, and then once daily until the hemoglobin and red cell counts became normal. The maximal reticulocyte response was obtained between the fifth and seventh days and varied in this series of cases from 168 to 472 per cent. The average of the entire group was 276 per cent, omitting the patients who received previous therapy which had absorbed the maximal reticulocyte peak. The authors experience indicated that only a temporary remission is obtained from liver therapy and that maintenance treatment is necessary to prevent another relapse. A complete hematologic remission was produced in intervals of from four to eight weeks and the majority of the patients treated showed an average daily gain of 1 per cent hemoglobin and 57,914 red cells from the average daily injection of 2.14 cc of equine liver extract.

Diagnosis of Diseases of Liver and Spleen—Yater and Otell describe a new method of visualization of the liver and spleen developed mainly by Radt and Oka. It consists in the intravenous injection of thorium dioxide sol, from which the radiopaque thorium dioxide is engulfed by the reticulo-endothelial cells of the body. Since these cells are most numerous in the liver and spleen, these organs are visualized better than other parts of the body. This method is a laboratory procedure and should in no way replace clinical methods of diagnosis. It may not be harmless, but except for the possibility of radioactivity contraindications are negligible. Reactions are few and are not serious. The results of this method alone were diagnostic of the nature of the lesions of the liver in twenty-four patients. Evidence suggestive of the nature of the disease of the liver or spleen was obtained in eleven, the nature of an undiagnosed abdominal mass was determined in seven and confirmation of the enlargement of the liver or spleen or both was obtained in thirteen. The method was valuable in ruling out lesions of the liver or spleen in twelve and supplementary information was obtained from it in eleven so that a working diagnosis could be made. The position of the diaphragm was established in two and the method was of scientific value in only two. No aid was obtained from it in eight, and in one patient the wrong diagnosis was made on the basis of the method. The authors state that the following points may be determined by means of this method: (1) the presence of enlargement of the liver or spleen, (2) the decision of the question as to whether a mass in the upper part of the abdomen is the liver, the spleen or something

else, (3) the presence of metastases in the liver, (4) the presence of a primary tumor, cyst or abscess in the liver, (5) in many cases the nature and extent of such intrahepatic diseases as cirrhosis and extensive scarring of the liver from syphilis, (6) the progress of such diseases of the liver, (7) the presence of free fluid in the abdomen, (8) the existence of such lesions of the spleen as tumor, infarct, abscess, fibrosis and leukemia, (9) the existence of rupture of the liver or spleen, (10) the position of the diaphragm, (11) the presence of accessory spleens and (12) possibly the presence of obstruction of the common bile duct

Infections of the Neck—Beck discusses infections of the neck, especially deep pus in the neck, and the surgical route in such cases. The source of such infection is in or about the tonsils. In connection with deep pus in the neck there is often an unrecognized thrombosis of the internal jugular vein which gives a fatal septicemia. The author presents an analysis of twenty-four cases of infection of the neck, all except two of which were treated surgically. For infection of the prevertebral fascia or retropharyngeal abscess he employed a direct incision of the pharyngeal wall through the mouth or an incision along the anterior border of the sternomastoid muscle lateral to the larynx, as recommended by Dean, for infection of the pharyngomaxillary, parotid and submaxillary space, an approach through the submaxillary space after elevating the gland, as recommended by Mosher, or a direct approach beneath the angle of the jaw without elevating the gland, for infection of the carotid sheath and visceral fascia, an incision along the anterior border of the sternomastoid muscle as for jugular resection, and for posterior triangle infection, an incision along or behind the posterior border of the sternomastoid muscle.

Laryngectomy and Intrinsic Cancer—The technic of Brandon differs from that of Mackenty in the manner of the incision and the method of drainage. The larynx is exposed through a straight midline incision beginning just below the hyoid bone and extending to the second ring of the trachea. This straight midline incision gives perfectly adequate exposure for skeletonization of the larynx in all cases of intrinsic cancer. Any slight advantage which the T-shaped incision may have in the way of exposure is more than offset by disadvantages when it comes to postoperative healing and the dangers of infection

Before the midline incision is closed, two small lateral incisions for drainage, about three-fourths inch long, are made parallel to the upper portion of the wound and just anterior to the sternocleidomastoid muscle. Two other lateral incisions large enough to admit a double drain are made opposite the trachea, just anterior to the sternocleidomastoid, for drainage around the lower part of the wound. A small rubber catheter drain tube with three openings in the center, close enough together to drain the center of the wound, is placed through and through the upper incisions from one side to the other of the deep wound. A double Mackenty drain tube wrapped in gauze and open only at its distal and proximal end is placed in each upper lateral incision, just below the through and through tube, and is pushed in near to the center of the wound. In each of the lower drainage incisions a double rubber drain tube wrapped in iodoform gauze, and with an opening about 1 cm from the distal end, is placed to the bottom of the wound pointing slightly inward and upward. The midline incision is then closed with parallel mattress stitches of heavy silk-worm-gut, following the Mackenty technic.

Local Anesthetic for Nose and Throat—From a study of the use of the hydrochloride of piperidinopropanedial diphenylurethane (diethane) as a local anesthetic for the nose and throat, Stitt concludes that the drug, if properly used, is a satisfactory local anesthetic to replace cocaine for all routine uses in the nose and throat. It may be used in considerably lower concentrations than cocaine, although the onset of anesthesia is somewhat slower. The resulting anesthesia is more lasting than that produced by cocaine and frequently much more striking. Its action on the ear drum allows an almost painless paracentesis. In a series of several hundred cases in which hydrochloride of piperidinopropanedial diphenylurethane has been used there have been no signs of toxicity and the drug has not produced the undesirable reactions sometimes found with cocaine. It is safe for routine use as a spray to relieve pain after tonsillectomy and is preferred for this purpose to acetylsalicylic acid.

Lycopodium Granuloma—Antopol states that Lycopodium, because of its fine spicules, has a tendency to become adherent to any tissue on which it is deposited and that on manipulation it may be forced beneath the surface. It is therefore possible for an operative specimen to become contaminated with spores of Lycopodium during removal. To demonstrate this, the freshly removed specimen from a patient operated on for acute appendicitis was intentionally handled with gloves which had been powdered with these spores. After the specimen had been dehydrated, embedded, sectioned and stained, microscopic examination revealed many of the spores completely embedded within the tissue. It is obvious that this may lead to an error in diagnosis. To avoid such an error it is necessary that the spores be found within giant cells or within a granulomatous lesion. The author reports six illustrative cases. Animal inoculation with the spores of Lycopodium clavatum resulted in the formation of granulation tissue after from two to six weeks, which on microscopic examination was not unlike the reaction in man, including the presence of the spores within the giant cells. Further experimental studies on the various phases of this problem are in progress. It is also possible that the crystals of magnesium silicate (talc) produce such lesions. This idea obtains support in the finding of the crystals within the giant

cells in the fistulous tract. The author presents a case which demonstrates the formation of minute talc granulomas in an otherwise normal appendix.

Leiomyoma of the Prostate—During the past year Dirl and Halpert observed three cases of solitary myomatous nodules of the prostate. They discuss these and the eight cases reported previously in the literature. Depending on size, location and concomitant changes in the prostate, they produced disturbances either of urination or of defecation. Seven of the patients had urinary symptoms only. The remaining four had primarily rectal manifestations. In most of the patients with urinary symptoms, the presence of the myomatous nodule perhaps only exaggerated the disturbances due to enlargement of the rest of the prostate. In none of these could the urinary difficulties be attributed to the myomatous growth alone although the growth arising in the prostate proper (mostly in the median portion) contributed to the distortion of the urethra. In the group of patients with rectal disturbances, the tumor obviously produced obstruction. Arising in the posterior portion of the prostate, it grew toward the rectum. The location of these leiomyomas with respect to the prostate and the surrounding organs suggests a genetic difference in the origin of the tumor. The available information is insufficient to ascertain the validity of this suggestion.

Relation of Suprarenal Cortex to Vitamins—Lockwood and Hartman determined the influence of cortical extract on vitamin A, B and C deficiency, respectively. Guinea-pigs were used in the vitamin C and rats in the vitamin B and A experiments. When administered by mouth, the cortical extract afforded no protection against avitaminosis C and B. However, when the extract was injected intraperitoneally, it (1) improved the growth curve and scurvy score in avitaminosis C, (2) improved the growth curve and delayed the onset of symptoms in avitaminosis B and (3) had no influence in ameliorating the symptoms in avitaminosis A. Suprarenal weights showed hypertrophy of the suprarenals in vitamin C and B deficiencies and atrophy in vitamin A deficiency. Hypertrophy was measured over a period of time after single suprarenalectomy in the vitamin C experiments. It was found that after single suprarenalectomy the hypertrophy increased as the interval of time after the removal of the first gland increased, measured

over an interval of from four to eight weeks. In the vitamin C series, after single suprarenalectomy the activity of the remaining suprarenal, as measured by its influence on the onset of scurvy, increased to a degree greater than is found with the two normal intact suprarenals. A decrease in this overactivity was noticeable at approximately the end of the third week after the operation. The injection of cortical extract containing cortin delayed the onset of symptoms in avitaminosis C and B but had no influence in avitaminosis A. Either cortin or some unidentified substance must be responsible for this effect. Because the extract is most effective (1) early in the experiment when some vitamin from the preexperimental period is still available in the organism and (2) when a partial protective quantity of the vitamin is fed the authors believe that cortin or some unidentified substance aids in the utilization of vitamins C and B. Since cortical extract retards the onset of the avitaminosis symptoms of vitamins C and B, they suggest that an ample supply of these vitamins would be advantageous in suprarenal cortical insufficiency.

Specific Dynamic Action of Protein and Its Value in Pituitary Disease—Goldzieher and Gordon determined the specific dynamic action of protein in 264 patients. Signs and symptoms of pituitary disturbances were present in 196. There were sixty-eight cases used as controls which included normal subjects as well as some presenting various nonpituitary endocrinopathies such as hyperthyroidism or hypothyroidism or ovarian deficiency. The basal metabolic rate was established by the usual technique and determinations were calculated according to the method of Benedict. The following morning a test meal was given consisting of the whites of three hard boiled eggs, a thin slice of toast and a cup of tea without sugar, cream or milk. After a rest of two hours, the metabolic rate was again determined and the difference between the basal rate and the reading after the test meal was compared. Every patient had at least two readings made at each time. Each patient was studied according to a routine procedure and the diagnosis made on the basis of a careful history of development, growth, nutrition and sexual function on thorough physical examination including the special fields of gynecology, gastroenterology and ophthalmology on anthropometric studies, roentgen observations whenever indicated especially of the sella turcica and bone development in children and on chemical studies. The average specific dynamic action in the pituitary cases was 4.47 against 16.3 in the controls, and the incidence of a specific dynamic action below 10 was 86 per cent in the pituitary cases against 21 per cent in the controls. In twelve cases the specific dynamic action increased after prolonged treatment with anterior lobe extracts together with small doses of thyroid. Patients having a pituitary tumor or an ovarian deficiency showed a specific dynamic action well above all others. Determination of the specific dynamic action after the ingestion of a small protein test meal is a valuable aid in the diagnosis of pituitary disease.

Hyperinsulinism Treated with Insulin—John reports the case of a woman who was subject to repeated attacks diagnosed as hyperinsulinism. She was treated with small doses of insulin (10 units) after meals with a view to forestalling discharge of that hormone by the pancreas. The results were notably favorable. Whether or not 10 units of insulin three times a day is the optimal dosage has not yet been determined. Perhaps a gradual increase to the point of tolerance might prove more effective in some cases. Another point to be determined by further study is whether training the pancreas to put out less insulin will stabilize the function of the pancreas, so that insulin may be discontinued. The author plans to reduce the amount of insulin gradually until it is eliminated completely.

Conduction of Labyrinthine Impulses—Aronson confirms the observation of Spiegel that, after strychninization of the posterior ectosylvian and suprasylvian convolutions in cats and dogs, stimulation of the labyrinth can produce epileptiform convulsions. Experiments were performed in which one labyrinth was destroyed and the previously mentioned cortical areas were strychninized on the same and then on the opposite side. In these experiments, rotation still produced epileptiform convulsions. These experiments led to the conclusion that each labyrinth is connected with the crossed as well as the homolateral cortex. After total severance of the posterior longitudinal fasciculus, rotation still caused epileptiform convulsions when the suprasylvian and ectosylvian convolutions were strychninized. The author concludes that labyrinthine impulses reach the cortical centers by way of the posterior longitudinal bundle and that there exist also other tracts outside these pathways for this conduction.

Trichomonas Vaginalis Vaginitis—In treating Trichomonas vaginalis vaginitis Holter thoroughly cleanses the vulva, vaginal wall, cervix and anal region with tincture of green soap and warm water. The vagina is cleansed with warm tap water, wiped as dry as possible and dried by holding a low pressure air current at the mouth of the speculum for a few minutes. The vagina and cervix are then sprayed with a 1:1,000 solution of hexylresorcinol by connecting a spray to the low pressure air current. A tampon soaked in solution of boroglyceride is then inserted high into the vagina. The vulva and thighs are then wiped dry and painted with a 50 per cent solution of glycerin. The tampon is removed the next day and

the patient takes a douche with 1 tablespoonful of tincture of green soap in 2 quarts of water. Douches should be taken morning and night on the two days following the treatment. The vulva and thighs are painted with the 50 per cent solution of glycerin after each douche. These treatments should be continued until the trichomonads are absent on at least three successive hanging drop examinations. When the treatments are discontinued, the patient takes lactic acid douches daily. During pregnancy, the local treatments can be continued as outlined, until about six weeks before term. After that time it is advisable to use 4 per cent mercurochrome instillations with a sterile catheter every other day. In resistant cases the vaginal walls and cervix may be painted with tincture of iodine instead of the solution of hexylresorcinol.

Bacteriophagy in Treatment of Infections—Boyce and his associates observed that they have not found dosage to be of great importance in the bacteriophage treatment of infections of superficial and deep tissues. If the results are not prompt they increase it hoping that an increased amount of bacteriophage may compensate for a possible lack of potency, but when the results are satisfactory they continue with the original dose. They have given as many as seven successive injections, in doses ranging from 0.5 to 5 cc, and have found, as did d'Herelle, that large doses were without harmful effects. The application of the jelly to open wounds is far more satisfactory than the older method of using moist dressings or of injecting fluid material into open cavities in which it could not be expected to remain but it is the authors' impression that the lysate is rather more effective. In the single case in which they used the intravenous route they bore in mind d'Herelle's warning that bacteriophage must be used in adequate dilution (from 1 to 2 per cent in quantities of 500 cc of physiologic solution of sodium chloride) and should be administered slowly, in order to avoid the risk of anaphylactic shock.

Immobilization of Normal Joints—Ely and Mensor review and attempt to determine just what pathologic changes may occur in the experimental animal following immobilization. They observed the following definite microscopic anatomic changes: 1 The cartilage shows a closer approximation of articular surfaces. 2 There is thinning, irregularity, fibrillation and in places vacuolization of the cartilage. 3 Fibrin plaques are evident between the surfaces of the joint apparently related to the synovial membrane. 4 The areolar tissue about the periphery of the joint becomes of a denser consistency and encroaches between the articular surfaces in places, causing a substitution of the cartilage with connective tissue type of cell. 5 No definite fibrous adhesions are demonstrable between the surfaces of the joint. The authors do not entirely agree with Muller, who, while confirming the anatomic observations of earlier investigators, stated that only extreme grades of immobilization give discernible changes. In their series the immobilization was not complete, as if the bone had been in a plaster-of-paris cast with skeletal traction, nor was the immobilization constant during the entire period. In spite of the absence of these factors, however, the fixation was complete enough to give the microscopic picture described.

Proximal Jejunal Loop in Posterior Polya Anastomosis—In dealing with the proximal jejunal loop after having satisfactorily completed the posterior Polya anastomosis, Lahey employs the following method. The ligament of Treitz is cut from its lowest insertion into the jejunum up to its origin in the mesenteric root. This permits of mobilization of the uppermost part of the jejunum, so that the proximal loop of jejunum now anastomosed to the stomach can be passed up through the slit made in the transverse mesocolon, and in this way the entire proximal loop of jejunum is brought above the mesocolon and is excluded from the greater general peritoneal cavity. While the true vascular root of the transverse colon is still above the junction of the jejunum with the duodenum, nevertheless there is less angulation of the proximal jejunum than when the proximal jejunal loop enters the greater peritoneal cavity at the jejunal fossa and is again passed upward out of the greater peritoneal cavity through a slit in the transverse mesocolon. It has the additional advantage that now only a single segment of intestine the distal jejunal loop emerges through the transverse mesocolon. Snug suture of the slit in the transverse mesocolon about the single loop of intestine is thus possible and the danger of hernia through this slit is lessened. The plan of placing the entire proximal loop of jejunum above the transverse mesocolon in a posterior Polya anastomosis has, if anything, not added to but diminished certain of the technical difficulties of this type of anastomosis after partial gastrectomy. In all the cases in which it has been employed, the anastomosis has functioned well, and any question of the need of entero enterostomy between the proximal and distal loops of jejunum has been eliminated.

Phenylmercuric Nitrate—Biskind treated seventy consecutive cases of infections of the vagina and the cervix with

phenylmercuric nitrate. A smear of the urethral secretion was taken as a routine. The vagina was opened with the usual bivalve speculum and a cervical smear was then made. Subsequently the entire vagina was cleansed and the cervical canal was wiped dry. Phenylmercuric nitrate was then instilled into the cervical canal with a cotton applicator and it was held in place while a cotton ball saturated with the medication was used to swab out the vagina. The applicator was then removed and a tampon the distal end of which was saturated with phenylmercuric nitrate was inserted. The patient was instructed to remove the tampon after twenty-four hours and then to begin the daily douche. Dilutions of 1:25,000 and 1:12,500 were used at first but it was soon evident that lower dilutions could be used with safety. Continued experimentation afforded sufficient evidence that optimal results were obtained by using a 1:1,250 solution, which, according to Weed and Ecker, is the saturation point for phenylmercuric nitrate in water. Favorable response to the use of this antiseptic was invariable in all the conditions encountered, both specific and nonspecific, except when Trichomonas vaginitis was the inciting agent. The character of the infection can be changed and rapid amelioration of the condition may be obtained often with but a single application of this antiseptic. The results of the use of phenylmercuric nitrate in this series ranged from rapid and complete clinical recovery to improvement sufficiently marked so that adjuvant treatment could be successfully applied.

Grain Itch—Kittredge presents two cases of grain itch, occurring in an epidemic of eight cases caused by contact with debris from infected wheat straw. The characteristic lesion of the eruption is an urticarioid wheal surmounted by a tiny central vesicle, which rapidly becomes lactescent or even puriform. The vesicles vary in diameter from 0.5 to 2 mm. When of the larger size, the cutaneous picture may strikingly resemble that of chickenpox. The distribution of the eruption varies but the neck and the trunk and, to a lesser extent, the arms and the legs are usually involved. The face may show a few lesions, but the hands and the feet are ordinarily exempt. Itching is invariably violent if not intolerable and as in scabies, is worse at night, making sleep difficult or impossible. Malaise, anorexia, nausea, vomiting, chilliness and a rise of temperature also may be experienced. Schamberg's ointment was applied for the acute stage. One of the patients was entirely well, and in the other the eruption had almost completely involuted, twelve days after treatment had been instituted.

*Significance of Vitamins in Practical Experience I. J. Harris—p. 367
Nervous Control of Abdominal Blood Vessels and Viscera D. T. Barry—p. 373
*Etiology and Prevention of Toxemias of Pregnancy G. W. Theobald—p. 376

Significance of Vitamins—Harris states that correct nutrition cannot be left to instinct, to the use of natural unspoiled foods, to a varied diet or to a process of free selection. Recent official reports show that no less than from 80 to 90 per cent of the elementary school population in London gave evidence of having had some degree of rickets, notwithstanding the decreasing severity of the disease. Statistical data have been collected to show that, under our climatic conditions, unless special prophylactic measures are taken, some degree of rickets supervenes in a large proportion of instances with an appreciable proportion of severe cases and that no common foodstuff contains sufficiently large amounts of the antirickets vitamin. Cod liver oil has proved a sterling remedy but has the disadvantage that it may be impracticable to give enough to ensure full protection in every case. Experience shows that the most certain remedy is *viosterol*. From a practical standpoint it is sometimes an advantage to use a food in which the requisite quantity of *viosterol* has already been incorporated by the manufacturers. Ultraviolet therapy presents difficulties in the administrative direction for "wholesale" prophylaxis. For curative treatment, *viosterol* is undoubtedly the method of choice, it can easily be given at a sufficiently high and precisely standardized level. When administering *viosterol* it is essential to adhere strictly to the correct dose, since overdosage gives rise to hypervitaminosis. Contrary to what is often supposed the toxic overdose for the human being is close to the optimal therapeutic dose. The author recommends a dose of 1,500 international units a day for ordinary prophylactic use, and 3,000 or a maximum of 5,000 units for curative treatment. Experience shows that smaller doses may be only partially protective. The minimal toxic dose for the infant is about 10,000 units. The author discusses the mode of action of vitamin D and condemns parathyroid treatment for infantile tetany and other conditions of calcium or phosphate deficiency arising from inadequate retention of food calcium and phosphate. Vitamin A cannot be regarded as a general anti-infective agent, although it is advisable to ensure that diets are adequately provided with it because the offspring receives but a moderate amount prenatally and in the milk. There is no evidence to support the suggestion that the prevalence of constipation and stasis is due to the lack of vitamin B. It is essential that all infants should be dosed with adequate vitamin C (orange juice), as this vitamin is destroyed to a greater or less extent during the pasteurization of milk.

Prevention of Toxemias of Pregnancy—Theobald believes it improbable that any one toxin could cause the widely varying symptoms associated with the toxemias of pregnancy, or that a number of separate toxins should originate in the products of conception. The fact that the hepatic lesions peculiar to eclampsia may be caused by dietetic or mechanical factors, or a combination of the two, disposes finally of the strongest argument in favor of a toxin of pregnancy. He suggests that the fetus affects the fixity of the internal environment and that all the toxic disorders may be regarded as deficiency diseases. It follows that there is no fundamental causal difference between ordinary morning sickness and eclampsia. This hypothesis is not contradicted by any known fact and is supported by the results of calcium therapy. If excessive salivation, vomiting, cramps, dermatitis herpetiformis, edema and other symptoms can be cured by the injection of calcium, it is logical to suppose that they are caused by its deficiency. The number of patients who have been treated is small, but the success that has attended calcium therapy in such a variety of conditions warrants its extended trial. A great disservice has been done to the science of dietetics by

those enthusiasts who stress this or that vitamin without considering the diet as a whole or the importance of personal hygiene. The author claims that a complete, well balanced appetizing and easily digested diet, rich in the vitamins and in calcium, iron and iodine, if given early in pregnancy, will prevent the onset of toxemias (but not always of albuminuria), although it may be necessary to increase the available amount of calcium by the injection of calcium gluconate. Indeed, it might be expedient and, in the end, economical to give routine injections of this mineral at the thirty-second and thirty-sixth weeks of pregnancy. He further believes that such a diet would increase the resistance of the woman to puerperal infection. The one advantage of this hypothesis, which is possessed by no other, is that it can be put to the test, and even under "field" conditions.

Mechanism of Immunity in Malaria—Stott discusses two cases of malaria which showed severe malignant tertian infection with a rate of approximately 50 per cent of the red cells infected and numerous sporulating bodies in the peripheral circulation. It is possible, therefore, that the mononuclear phagocytosis of parasites normally takes place in the fixed reticulo-endothelial cells, which become "unfixed" or "free" in the blood only in the severest infections when there is an excessive stimulation of these reticulo-endothelial cells. The appearance of sporulating bodies in the blood observed in these cases is further evidence of the severity of the infection, for this phenomenon also usually takes place in the recesses of the reticulo-endothelial tissues. The clinical jaundice that was present is a reflection of the severe destruction of the red cells by the malarial parasites. As regards the type of parasite phagocytosed sporulating bodies were far more frequently observed in the mononuclear cytoplasm than ring parasites. It was easy to recognize such sporulating bodies when they were still within a phagocytosed red cell. It was frequently a matter of conjecture whether bodies of the size of individual spores scattered throughout the cytoplasm were or were not the semidigested remnants of a previously phagocytosed sporulating body. It could not be expected that the typical blue and red spore staining would be recognized in such a semidigested state, but the closer the number of such bodies approximated to fourteen and the more bunched they were together, the more likely it was that they were spore remnants. Sometimes the phagocytosed malignant tertian rings were within phagocytosed red cells and sometimes they were free in the mononuclear cytoplasm. Probably such free rings were mostly left behind after the red cell had been digested—but several such rings were free in the cytoplasm unsurrounded by any unstained vacuole and, moreover, they showed an excellent staining reaction and not a washed out or indiscriminate stain, which one might expect if the ring was semidigested. It is possible, therefore, that merozoites may at times be phagocytosed directly from the serum after leaving the breaking down red cell containing a sporulating body and before reaching a new red cell—and may indeed develop to some extent in the mononuclear cytoplasm itself. There is no doubt that small rings are found in large mononuclears, not surrounded by a vacuole and giving the impression of health and vigor rather than of semidestruction from digestion, by reason of their distinctive chromatin and protoplasmic staining reaction. Large mononuclear cells

may therefore show their phagocytic power in malarial, even in the peripheral circulation of severe human cases, by the presence of (1) pigment, (2) rings and (3) red cells normal or dehemoglobinized and infected or noninfected with sporulating or, less commonly, with other forms of malarial parasites

Operation for Drainage of Pleura—Fraser describes an operation which was originally designed for a case of malignant growth of the pleura in which the effusion collected so rapidly that aspiration had to be repeated every twenty-four hours. He decided on continuous drainage. Under local anesthesia with a 5 per cent solution of procaine the skin and the tissues right down to the periosteum of the eighth rib in the mid-axillary line were infiltrated and an incision was carried right down to the bone, $1\frac{1}{2}$ inches in length. An ordinary mastoid retractor was then inserted to hold back the soft tissues and the periosteum cleared from the rib over about one-half square inch. A trephine corresponding in diameter to the largest size tracheotomy tube was then used to make a hole through the center of the rib. Through the hole thus made the pleura was infiltrated with procaine, after which a pair of sinus forceps was inserted through the soft structures and the pleural cavity opened. The blades of the forceps were opened and rotated within the hole to tear the pleura open for admission of a tracheotomy tube. Only one tube was used and its curved end was directed downward, it entered smoothly and lay snugly flush with the rib, to which it was fastened by a silk suture through the periosteum. On removal of the mastoid retractor, the soft tissues closed in to some extent and the gap left was lightly plugged with sterile gauze to exclude air but to allow free drainage. The author believes the advantages of this method are: 1 The small size of the wound and minimal incision. 2 The bloodlessness of the method if epinephrine is used with procaine hydrochloride. 3 The absence of mutilation of the rib. 4 No projection from the wound by way of drainage. 5 Absence of irritation of the pleura or reflex coughing with the tracheotomy tube lying flush against the wall of the thorax within. 6 The rapidity of the method compared with resection of a rib.

Excretion of Prolan—Parkes and White injected 30, 50 and 100 mg of prolan into gonadectomized rabbits, or about three, five and ten times the amount required to produce ovulation with certainty in an estrous animal. After prolant injection, urine was collected for times up to nine hours. Collection for more than nine hours produced highly toxic samples. Of two animals receiving 30 mg of prolant, one gave active urine nine hours later, so that rather less than one-third of the hormone appears to have been excreted during this time and recovered. Of two tests on one-fourth of the urine obtained nine hours after the injection of 100 mg of prolant, one was positive and the other negative. In other experiments, injection of all the urine and also of half of the urine collected nine hours after injection of 100 mg produced positive reactions. These results suggest that about one-third or less of the material is excreted in nine hours. It would thus appear that the blood threshold, if any, which the hormone must attain before excretion can begin is comparatively low. The results suggest that excretion continues up to nine hours

Thus, in the groups receiving 30 and 50 mg of prolant the urine appears to be more active after nine than after six or seven hours. After the administration of 100 mg of prolant, active urine was obtained during the first three and also between three and nine hours. The authors state that a pregnant woman excretes from 500 to 1,000 rabbit units of prolant a day, or, roughly, 10 units a day per kilogram of body weight. The amount which can be excreted by a rabbit is therefore of the same order as that which actually is excreted by a woman. It may thus be concluded that the failure of the pregnant rabbit to excrete prolant is due not to an inability on the part of the kidneys but more probably to the lack of the hormone in the blood.

Laboratory Diagnosis of Typhoid Infections—In order to determine the practical value of Felix's method of differentiating between inoculation and infection agglutinins, Compton and Sand tested, without any special selection, some seventy blood specimens sent to their laboratories for routine Widal examination during nine consecutive months of 1931. To this end they supplemented their two ordinary methods of laboratory serodiagnosis: (1) hemoculture with the clot and (2) quantitative microscopic agglutination toward H emulsions of T A and B organisms with the serum, by (3) testing in addition the agglutinating action of the serum against an O emulsion of T. They observed that in the presence of negative and non-diagnostic (1/50) results of sero-agglutination the diagnosis is improved by approximately 4 per cent when a sensitive phenolized O emulsion is included in the technique of the Widal test. It is improved by approximately 10 per cent when systematic hemocultures are carried out with all specimens the clots being utilized to this end. Whether a sero-diagnosis improved to the extent of 4 per cent may or may not be thought a justification for complicating laboratory reports with the vaguer diagnosis of 'enteric group' infection is an open question. The bacteriologist and the clinician can only decide that between them. The greater improvement and precision of laboratory diagnosis arising from the systemic carrying out of hemocultures cannot be sufficiently insisted on. Yet this is far from being the general practice of laboratories in Egypt. In the authors' experience, practitioners do not avail themselves sufficiently of the help which the laboratory can afford by bacteriologic examinations of specimens of feces and urine in obscure typhoid conditions characterized by negative or doubtful Widal results. The agreement of 10 per cent of Widal positive specimens showing supplementary evidence of the presence of inoculation agglutinins and the calculated approximately floating proportion of 10 per cent of the population being inoculated within two and one-half years is striking.

Ascorbic Acid in Scurvy—Schultzer presents a case of scurvy in a man of 68 who was cured with ascorbic acid. The daily intravenous injection of 40 mg of ascorbic acid resulted in rapid recovery from the scurvy. He believes it doubtful whether the 40 mg of ascorbic acid if given by mouth would have produced the same effect, especially in view of the fact that the patient suffered from gastric achylia.

Sensitiveness of the Wassermann Reaction—Fairbrother investigated the practicability of Wyler's modified reaction of the Wassermann reaction in a laboratory, in which some 500 serums are examined weekly. Various serums giving either negative or doubtful results when tested by his usual laboratory technique were selected for examination. This consisted of a further test in which increased strengths of serum were used. He observed that undiluted (1/1) serum was unsatisfactory, owing to the fact that (1) in several instances

at this strength the serum exhibited distinct anticomplementary properties and (2) that the amount of serum required for the test was too large for the many specimens received. Therefore it was decided to compare the results obtained with a large series of serums diluted 1:2 and 1:5. The results obtained support the assertion of Wyler that the sensitiveness of the Wassermann reaction can be increased without loss of specificity by increasing the quantity of the serum to be tested. For routine work, however, it is necessary that a definite dilution or series of dilutions should be adopted. An increase in the sensitiveness of the reaction is a most useful step, especially in treated cases. One objection might be that another serum dilution in the quantitative method would make the test too cumbersome. This may be so, but it seems preferable to replace the largest dilution, such as 1:45, and substitute a dilution of 1:2. Thus a series of dilutions of 1:2, 1:8 and 1:32 would be more valuable than a series of 1:5, 1:15 and 1:45.

Hypoglycemic Angina—Sippe states that it has been said that a blood sugar reading of 0.08 per cent does not constitute sufficient evidence to warrant a diagnosis of hypoglycemia. On the other hand, undoubted symptoms of hypoglycemia can occur when the blood sugar is much higher. In his experience a blood sugar reading of 0.08 per cent should always be looked on with suspicion. The diagnosis is verified by the clinical history and the therapeutic test which follows the administration of dextrose. The person with acetonemia lacks the power of utilizing the dextrose obtained from an average diet and needs the addition of dextrose as well as a reduction of the intake of fat in spite of a normal blood sugar. It would appear that the changes in the electrocardiographic record must now be regarded as giving important diagnostic criteria in hypoglycemia and acetonemia and afford a valuable indication of the results of treatment. The importance of this observation is obvious, since failure to recognize the condition and to institute appropriate treatment has left the way open for the diagnosis of coronary thrombosis with its grave prognostic significance. The author describes four cases of hypoglycemia and one of ketosis which showed anginal symptoms suggestive of cardiac disease. The electrocardiograms showed characteristic changes. The author concludes that changes in the cardiac muscle are only one of the many manifestations of hypoglycemia and ketosis. A great deal of evidence has been collected to show that these conditions are of extreme importance in the production of sinusitis and nontuberculous pulmonary fibrosis. The electrocardiographic changes in hypoglycemia and ketosis consist of any of the following combinations: (1) flattening or inversion of the P waves, (2) low voltage QRS complexes, (3) depression of the ST interval, (4) flattening of the T waves.

 *Syphilis of Esophagus E Watson Williams—p 310

Syphilis of Esophagus—Watson-Williams describes four cases of syphilis of the esophagus and two in which that diagnosis appeared correct. Dysphagia was the first symptom

four of the six showed wasting, and only one had real pain. The local appearances include (1) general esophagitis tending to affect the middle two fourths of the esophagus, but in one case the whole, (2) maceration of the epithelium, with longitudinal desquamation going on to complete shedding of the epithelium and (3) formation of leukoplakic patches consisting of thickening of the epithelium only. In 350 consecutive esophagoscopies the appearance of general esophagitis affecting the middle two fourths of the esophagus and maceration of the epithelium were not seen except in the six cases described. There were eleven cases of aneurysm causing dysphagia during the period covered by these esophagoscopies.

 *New Sign of Lumbago G S Demianoff—p 1883

Sign of Lumbago—Demianoff describes a sign that permits the differentiation of pain originating in the sacrolumbalis muscles from lumbar pain of any other origin. The sign is obtained by placing the patient in dorsal decubitus and lifting his extended leg. In the presence of lumbago this produces a pain in the lumbar region which prevents raising the leg high enough to form an angle of 10 degrees, or even less, with the table or bed on which the patient reposes. The pain is due to the stretching of the sacrolumbalis. To make certain that the pain is not due to sciatica (Lasegue's sign), the patient's leg is lifted a second time. This time the physician fixes the pelvis on the same side by pressing heavily with his hand on the region of the homolateral anterior superior iliac crest. The fixation of the pelvis prevents the stretching of the sacrolumbalis and permits raising the leg to an angle of 90 degrees without, or practically without, the production of lumbar pain. If the pain produced by raising the leg is due to sciatica it is not suppressed by fixing the pelvis, as this does not prevent the sciatic nerve from being stretched. The more acute the angle (between the leg and the table) at which lumbar pain is first experienced, the more severe is the involvement of the sacrolumbar muscle. The test should be performed on both legs. This sign of lumbago is usually manifest on both sides but the angle to which the legs can be raised may vary, as the muscle pain may be more intense on one side. If lumbago and sciatica coexist on the same side, the author's sign is negative on that side but it will be positive on the other side. In the rare case of simultaneous lumbago and sciatica on both sides the author's sign will be excluded by Lasegue's sign.

 *New Clinical Picture of Atypical Purpura Hemorrhagica Associated with Nodular Tuberculosis of Spleen A Omodei-Zorini—p 790

Atypical Purpura Hemorrhagica—Omodei-Zorini made a study of two women patients presenting atypical purpura, nonthrombopenic but thrombasthenic in type, associated with nodular tuberculosis of the spleen. The two patients developed hemorrhages of the skin and mucosae during premenstrual periods and during the spring season, and one of them also showed hemoptysis. In both cases the tuberculosis was latent and the spleen was involved in the form of chronic miliary tuberculosis in one patient and of an isolated caseous nodule in the other. In the second patient the author was able to isolate a tuberculous strain of attenuated virulence and of human origin. He believes that two concomitant factors account for this condition: a predisposing congenital factor of thrombasthenia and an acquired toxic infective tuberculous factor. In both cases the splenectomy interrupted the produc-

tion of tuberculous toxin and helped to stop the hemorrhagic manifestations. Tuberculin treatment reduced the fever and finally aided in establishing a lasting cure.

Radium Treatment of Inoperable Carcinomas of Rectum.—Schreus resorted to protracted roentgen irradiation and to radium treatment by contact in inoperable carcinomas of the rectum and in those no longer amenable to radical ray treatment. The radium is applied in the intestine. Since strong reactions are not desired, the author gives a first dose of from 500 to 600 mg. element hours by means of a brass container 3 cm. in length and having a wall thickness of 1 mm. The radium container is introduced with the aid of the rectoscope and is fixed in place by adhesive tape. The radium is introduced from three to four times, at intervals of from eight to ten days. This procedure generally produces a mild reaction on the mucous membrane and often a noticeable retrogression of the carcinoma. After from two to three months, a new series of radium treatments may be given. This treatment may be combined with protracted roentgenotherapy according to Courty's method with a focal dose of from 2,000 to 4,000 roentgens. In order to avoid severe reactions, frequent controls with the rectoscope are advisable. The author found that favorable palliative results may be produced with this method, for not only do the hemorrhages cease and does the tumor decrease but the patient's general condition also improves. Cicatrization may produce strictures that necessitate the formation of a preterminal anus. The author's results were such that an artificial anus could be dispensed with. He is unable to say to what extent the protracted roentgen-radium treatment would prove useful in cases that are not yet as far advanced as those treated by him. He thinks that surgical treatment with subsequent prophylactic irradiations should be the method of choice in operable cases but that in the more advanced cases the described method is the best, since it is sufficiently effective and yet preserving.

Irradiation of Ovarian Carcinomas.—According to Vogt the surgical treatment of operable ovarian carcinomas is generally followed by a prophylactic roentgen irradiation with the full carcinoma dose given as soon as the wound is healed. In case of a relapse the carcinoma dose is again applied, but the interval between the roentgen treatments should be at least three months. In exceptional cases a third carcinoma dose of roentgen rays may be given after another three months. The incompletely removed ovarian carcinomas, or the inoperable ones, the inoperability of which has been established by exploratory laparotomy with biopsy and microscopy, are treated by the author with a combination roentgen-radium treatment. From three to four weeks after the operation, radium (from 1,800 to 2,200 mg. hours) is introduced into the uterus. A few days later this is followed by roentgen irradiation with the full carcinoma dose. The second intra-uterine radium treatment is given six weeks after the first, and the third is given after another six weeks. This third radium treatment is again followed by an irradiation with roentgen rays. The author gained the impression that the combined roentgen and radium treatment gives better results than the roentgen irradiation alone, and he recommends the application of this method.

Intestinal Helminths and Their Extra-Enteral Occurrence.—Brüning mentions several types of *Taenia*, *Ascaris lumbricoides*, *Oxyuris vermicularis* and *Trichocephalus dispar* as the helminths most frequently found in the Baltic provinces of Germany. He points out that the complications which may be caused by these helminths make it necessary to expel them. For the expulsion of *Taenia* he recommends extract of male fern, and he treats ascariasis, oxyuriasis and trichocephaliasis with oil of chenopodium. However, these anthelmintics are effective only as long as the helminths are present in the gastro-intestinal tract, for these intestinal parasites may also lead an extra-enteral existence. The larvae of ascarides, for instance, may pass through the veins of the intestinal tract to the liver, into the heart and lungs, and up the bronchi until they reach the pharynx. After being swallowed, they again enter the gastro-intestinal tract, in which they grow into the adult form. Such an extra-enteral course of development is not known about *Oxyuris* and *Trichocephalus*, and the extra-enteral occurrence of *Taenia* is a great rarity, although cases have been reported in which a tapeworm was found in the gallbladder and even reached the liver. The occurrence of *Taenia* in the abdominal cavity or in an abscess of the abdominal walls likewise has been reported. From the duodenum, ascarides occasionally enter into the biliary tract. Occasionally they penetrate the intestinal wall, particularly, in cases of ulceration or following operations, and then cause peritonitis, but there is also some evidence that even the intact intestinal wall may be penetrated by *Ascaris*. *Oxyuris* has been found in the surroundings of the anus or of the genitalia, or in the region of the coccyx, for it is known that the females emerge from the intestine to deposit their eggs. Through the vagina they may travel upward and reach the oviducts or the peritoneum. Extra-intestinal occurrence of *Trichocephalus* is not known. The author thinks that, in most instances of extra-enteral occurrence of helminths, cure can be effected by surgical treatment.

Sedimentation Reaction in Acute Infectious Diseases.—Curschmann reports his experiences with the sedimentation reaction in a number of acute infectious diseases. In typhoid the sedimentation speed was either reduced or normal during the first week. During the second week there usually developed an acceleration which persisted during the third, fourth and fifth weeks. During the sixth week the values decreased, to remain only slightly accelerated, and this slight acceleration frequently persisted throughout a prolonged convalescence. Paratyphoid was characterized by similar changes. In *Alcaligenes abortus* infection the author gained the impression that in the first stages the sedimentation is either low or normal and that during the subacute or chronic stages it is usually increased. He considers the sedimentation reaction a valuable aid in the diagnosis of *Alcaligenes abortus* infection, for the low sedimentation during high fever is even a more frequent symptom than is leukopenia with lymphocytosis and monocytosis. Observations on cases of dysentery convinced him that in this disorder the sedimentation speed is of no particular value. In scarlet fever, he found it more uniform. The sedimentation was considerably increased at the onset. Uncomplicated cases

showed a decrease as soon as the fever decreased and, with advancing convalescence, normal values were reached again gradually. A persistence of the high values or a further increase during the time when the fever was decreasing indicated a complication or a superinfection. Measles was characterized by a high sedimentation speed at the beginning, but, as soon as the exanthem faded and the temperature fell, there was a rapid decrease, except when complications developed, in which case the sedimentation either remained high or increased again. During the first stages of the various forms of tonsillitis or of diphtheria, it was observed that the sedimentation did not increase as rapidly as did the number of leukocytes. Leukocytosis and deviation to the left are therefore of greater diagnostic value than the sedimentation reaction. At the severest stage of these infections, the sedimentation and the leukocyte formula showed practically the same behavior, but during convalescence it could be observed that an increased sedimentation often persisted for a considerable time after the fever, leukocytosis and deviation to the left had disappeared.

Gastro-Enteritides Caused by Eggs—Muller discusses his studies on micro organisms resembling those of typhoid, but nonmotile like those of dysentery. He made two cultures from the feces of patients who developed gastro-enteritis after eating potato salad and blood sausage, and two from the ingested foods. He found that the four cultures were of the type *Bacterium gallinarum*, which is the cause of chicken enteritis but so far has not been considered pathogenic for human subjects. However, it is known that this bacterium has four variants, and further studies disclosed that the four cultures were of the type referred to as *Shigella flexneri*. Of four chickens that were fed with the cultures, three died in less than five days, and the pathogenic micro-organism was isolated from their heart blood; one of the animals recovered. The author concludes that the potato salad eaten by the patients contained infected eggs. The presence of bacteria in hen's eggs was demonstrated as far back as 1911, and their pathogenicity for human subjects has been denied by some but demonstrated by others. The author thinks that febrile diarrheas of this origin may have been overlooked so far, because of their mild course, or a thorough bacteriologic investigation may have been neglected. He relates cases of gastro-enteritis in which atypical forms of Gartner's bacillus were the cause. The food that caused the disturbance had been prepared with the fresh white from a hen's egg and with the white of a duck's egg that had been kept for several days. The author thinks that the latter was the source of the infection, and he assumes that the storage of the egg white, by permitting a multiplication of the organism, was an essential factor. He also cites other reports on the transmission of enteritis organisms (types Gartner or Breslau) by eggs from ducks or chickens.

Treatment of Pernicious Anemia with Duodenal Juice—In comparing the value of liver therapy and of stomach preparations, Kühnau points out that extracts of the gastric mucous membrane are as effective as the best liver preparations and that in cases of funicular myelitis the stomach extracts are even superior. The fact that in pernicious anemia not only the chemistry of the stomach but also the function of the duodenum and of the entire small intestine is impaired justifies the question whether the upper portions of the intestine do not produce an antianemic principle. Studies on this problem have given contradictory results, but the author reasons that it ought to be possible to compensate for the cessation of the production of ferment in the duodenum during pernicious anemia by the administration of normal duodenal juice. Moreover, the duodenal juice always contains some bile and there is a possibility that the antianemic principle of the liver is carried with the bile into the intestine, so that the duodenal juice ought to be doubly rich in the antianemic principle. The author resorted to the administration of normal duodenal juice in cases of pernicious anemia which proved refractory to liver therapy and in which the anemia had become extremely severe. After the production of duodenal juice has been stimulated in a healthy subject, from 40 to 200 cc of it is withdrawn by means of the duodenal tube, and with the aid of a stomach tube, this juice (200 cc) is introduced into the stomach of the anemia

patient. Then 5 cc of diluted hydrochloric acid and two teaspoonfuls of dextrose are mixed in 200 cc of water, and this mixture is given to the patient. The procedure is comparatively simple and vomiting is never observed. On the basis of results obtained with this method, the author concludes that in cases in which other methods fail this procedure may yet be effective. He suggests that the duodenal juice at first be given three times each week, and later, after some improvement has been obtained, once a week.

Dangers of Overdosage of Borderline Rays—Kolrep's irradiation experiments on young rats corroborate former tests, in that they demonstrate that borderline rays are not harmless. If applied in large doses, they inhibit the growth of bones. A tabular report indicates that an injurious effect may become manifest after the application of a total dose of 2,000 roentgens. However, a sure impairment of the bone growth in all animals requires a total dose of from 3,200 to 3,500 roentgens. Another table indicates that irradiation begun at an early age apparently produces no greater impairment of bone growth than is the case if irradiation is begun in slightly older animals. The irradiation with the large doses produced a temporary epilation. The latter was the more pronounced in animals in which the intervals between irradiations were short. In the evaluation of these tests the author points out that roentgen rays may cause impairment of the growth of bones. She reviews experiments which indicate that the harmful dose is much lower for roentgen rays than for borderline rays, but, although the therapeutic dose of the borderline rays is much higher than that of roentgen rays, sight should not be lost of the fact that borderline rays may become harmful if given in excessive doses, and particular care should be taken whenever the growth zones of bones are exposed to irradiation.

Investigations on Immunity in Whooping Cough—Kairies and Goetze made studies on fourteen children having whooping cough and on fourteen healthy children who had been vaccinated against whooping cough. They found that the complement fixation reaction with the Bordet-Gengou bacillus was strongly positive in thirteen children having whooping cough and that it was doubtful in one child. Antibody formation was not demonstrable in four healthy nurslings who had been vaccinated, but complement fixing antibodies were demonstrable beginning with the eighth day after the first injection of vaccine in all children who were vaccinated after they had passed the first year of life. The reactions reached their maximum between the tenth and twenty-fifth days. In four of the children the complement fixation reaction had become negative again five weeks after the first injection. The serologic conditions seem to indicate that, particularly in nurslings, the prospects of a successful vaccination are doubtful. On the basis of theoretical considerations, the vaccination of children presenting allergic reactions, of those whose defense mechanism is impaired and

of those suffering from other bacterial infections, should be dispensed with. Complement fixation reactions with the Bordet-Gengou bacillus may occur also in the serum of patients having disorders other than whooping cough. Moreover the serum of children vaccinated with Bordet-Gengou bacilli may give temporarily nonspecific reactions with Wassermann antigens, gonococcus vaccines, staphylococci, colon bacilli and influenza bacilli. The occurrence of nonspecific reactions is largely dependent on the reaction capacity of different individuals. A better differentiation of the various receptors that are contained in the serum can probably be effected by an elective absorption.

Metabolic Studies in Glycogen Storage Disease—Heriz made metabolic studies on a boy, aged 11, who has glycogen storage disease (called also glycogenosis, von Gierke's disease and so on) and who has been under observation for several years. It was found that the nitrogen exchange was not increased. The amino acid metabolism was normal, and the gelatin-water tolerance test (according to Morawitz-Mancke) disclosed no abnormalities. These observations are important for the differentiation of glycogenosis from cirrhotic disturbances of the liver. The results of the liver tolerance tests with amino acids on the one hand, and with insulin sugar-water (Althausen-Mancke) on the other hand, correspond to each other, and the prolonged increase in the fat content of the blood following a fat tolerance test in patients suffering from glycogenosis likewise agrees with this. The creatine-creatinine elimination was found to be unusually high. The examination of the blood serum and of the urine revealed a temporary acidotic tendency in the metabolism. The water exchange was not noticeably disturbed in this case of glycogenosis, although other patients having glycogenosis have shown an abnormal water economy. The author reaches the conclusion that in glycogen storage disease it is not so much the liver that is diseased but that there is a disturbance in the metabolism which brings into prominence the storage of glycogen in the liver and in other organs. In the metabolic equilibrium there is a shifting toward polymerization. An increased elimination of urobilin bodies, which is the most exact indicator of impairment of the liver, has never been observed in glycogenosis.

Electrocardiographic Studies in Hyperthyroidism—Misske and Schöne report electrocardiographic studies in 113 patients with hyperthyroidism. The severity of a case was estimated by determination of the basal metabolic rate. The highest rate in any case was +107 per cent. Two hundred electrocardiograms were studied. Disturbances of the cardiac rhythm were frequent. The pulse varied between 70 and 130 per minute. Bradycardia with a pulse below 70 was observed in four patients, in one of these there was a pronounced hyperfunction of the thyroid and a basal metabolic rate of +42 per cent. Sinus tachycardia was noted in only five cases, all of which were typical instances of exophthalmic goiter with a basal metabolic rate ranging between 87 and 90 per cent. Sinus arrhythmia was found in practically all the graphs. Extrasystoles were rather unusual. There were two instances of

auricular and two of ventricular extrasystoles. Auricular fibrillation was present in twelve cases. The disturbance disappeared after surgical removal of the thyroid. The authors were not able to influence fibrillation by internal therapy. Disturbances in conductivity were rare, only three cardiograms showing a blocking of the sinus impulse. The time of conduction between the auricle and the ventricle oscillated, in the majority of the cases, between 0.12 and 0.19 second. The authors did not see an instance of a complete block or of a disturbance of intraventricular conductivity. In their opinion, the duration of the systole was conditioned by the frequency of the pulse: the faster the pulse, the shorter the duration. The study of an individual complex revealed a rise of the P wave in thirteen graphs, of the T wave in thirteen and of the ventricular phase in twenty-nine. A simultaneous rise of the P and T waves was recorded in only six graphs. This is opposed to observations of previous workers who considered the simultaneous rise in the two waves characteristic of exophthalmic goiter. The authors have seen this sign quite frequently in neurasthenic persons. They have gained the impression that sinus arrhythmia is a fairly constant sign in thyroid hyperfunction. All the cases exhibiting fibrillation belong to the severest type of thyrotoxicosis, a fact suggesting that the damage to the heart was of a purely thyrogenous origin. No instance of permanent arrhythmia of the pulse was noticed in cases in which a thyroidectomy was performed. In one case radium application was followed eight days later by fibrillation. The authors conclude that fibrillation of thyrotoxic origin is best treated by strumectomy.

Pathogenesis of Anxiety in Angina Pectoris—Hausner and Hoff state that the relationship between the anxiety occurring in an attack of angina pectoris and in edema of the brain stem was suggested to them by the following clinical observations. A young man, in whom Denk removed a cyst of the left cerebellar hemisphere developed four hours later a sense of anxiety and a feeling of impending death. This lasted four hours and disappeared without giving rise to any disturbance in the cardiovascular or the central nervous system. Two patients, in whom a cerebellar tumor was removed developed shortly after the completion of the operation a sense of anxiety and of impending death. This was accompanied by bulbar signs, such as blurred and double vision and a characteristic disturbance of the speech. Both died a short time later. Postmortem examination revealed edema of the lower portion of the pons and of the medulla oblongata on macroscopic and microscopic studies. The similarity of their anguish to that of patients having an attack of angina pectoris was striking. The authors next report postmortem observations on nine patients whose death was caused by coronary thrombosis. Six of these exhibited symptoms of anguish during the anginal attacks and five presented an occlusion of the left coronary artery. In five of the six last mentioned, edema of the stem of the brain was found on macroscopic and microscopic examination. On the other hand edema of the brain was not found in patients dying of various forms of cardiovascular disease other than angina pectoris. The authors ligated branches of the coronary artery in sixteen dogs and found edema on macroscopic and microscopic examination in ten. They feel that they have advanced sufficient proof to substantiate the suggestion that the feeling of anxiety and a sense of impending death occurring in an attack of angina pectoris are the result of edema involving the lower third of the pons and the medulla oblongata.

Cardiac Complications of Grip—Egedy has studied 100 cases of grip since 1929 and found that twenty-seven of these exhibited signs of cardiac involvement. Of the twenty-seven patients presenting cardiac complications, twenty-one gave electrocardiographic evidence of the disorders. The study of these twenty-one patients revealed that approximately 50 per cent of the alterations were due to a lesion of the path of conduction and about 25 per cent to a lesion of the myocardium and the coronary arteries. These figures do not include instances of bradycardia for the reason that the author is not certain whether the latter is caused by the toxic blocking effect on the excitability of the sinus nodes or by extracardiac causes. He had not observed any lesion of the endocardium or of the pericardium. The cardiac symptoms not infrequently may have

their onset simultaneously with the onset of fever and be demonstrable in electrocardiograms. Approximately two thirds of all cardiac complications occur after the disease is over or still later during the convalescence. The author points out that physical examination alone is incapable of detecting many cardiac complications. Retardation of auricle conductivity as well as the appearance of atrioventricular rhythm will not give physical signs save for bradycardia and positive venous pulse in the latter. Mild lesions of the myocardium likewise do not produce physical signs. The electrocardiogram often reveals surprising information in this group of cases. The therapeutic indication in such cases is absolute rest. Intravenous injections of dextrose and cardiazol are of value. Strophantus and digitalis are exhibited in the presence of decompensation. The prognosis is favorable, all the symptoms disappear in from two to six weeks, and the sinus rhythm and cardiac activity return to normal.

Parathyroidectomy in Ankylosis of Vertebral Joint—Jasienksi agrees with Leriche that the removal of the parathyroids in ankylosis of the vertebral joints is beneficial and should not be delayed even to await a rise in the calcium of the blood. He operated on four patients with ankylosis, three men and one woman, ranging in age from 27 to 45 in whom the duration of the ankylosis averaged fourteen months. Roentgenograms disclosed acute involvement of the processes of the vertebral joints, narrowing of some of the joints and the presence of ridges on the surfaces of some of the vertebrae. General examination of the patients revealed no changes in the respiratory tract, the circulation and the abdominal cavity. After operation the patients showed almost instant subjective and clinical improvement, which has persisted. In operating the author endeavored to adhere strictly to the recommendations of Chisolm and Ameline. He believes that their method is best, since the collar incision of Rocher permits both sides of the thyroid to be seen and allows observation of the parathyroids if found necessary.

Diseases of Liver—Barkhash emphasizes the intensive study of early forms of hepatic diseases with the view of preventing their passing into incurable types, such as cirrhosis or acute yellow atrophy. The early diagnosis of hepatic disease is made difficult by the absence of reliable functional tests. As a minimum of laboratory investigation in the study of hepatic function the author suggests (1) determination of galactose in the urine and of sugar tolerance after dextrose and levulose, (2) determination of the amino-acids in the blood and urine, (3) determination of bilirubin and cholesterol in the blood, (4) determination of biliary acids in the urine and of bile pigments in the urine and in the blood (5) roentgen study of the gastro-intestinal tract and cholecystography and (6)

esophagoscopy (for the detection of varices). A careful history is of the greatest importance. The early forms of hepatic disease are reversible and their timely recognition enables one to bring about the restoration of normal function. This is true not only of hepatitis without jaundice and with mild disturbance of hepatic function but of precirrhotic states with a profound disturbance of most of the liver functions as well. While isolated lesions of the liver or the bile tracts undoubtedly exist as such, more frequently the latter lead to the involvement of the liver, and vice versa. The author regards the so called hepatolienal syndrome as a precirrhotic state which not infrequently, passes into a typical cirrhosis of Laënnec, the patient for a long time preserving fair health and working capacity. The most important therapeutic measure in chronic hepatitis and in precirrhotic states is a liver-sparing diet, e. g. one rich in carbohydrates and limited as to albumins.

Pathogenesis of Angina Pectoris—Kudrin states that, of 500 instances of sclerosis of coronary arteries found by him on postmortem, only 50 offered a history of attacks of angina pectoris. These figures militate against the theory that coronary sclerosis is the direct cause of anginal attacks. On the other hand, the author points out that Neuberger found coronary sclerosis present in all of his thirty-three patients suffering from angina pectoris, Osler in thirteen out of seventeen (76.5 per cent), and Romberg in twenty out of twenty-eight (71 per cent). The author found in his postmortem studies frequent narrowing of the lumen of the coronary arteries and, at times, occlusion. Chronic aneurysm of the heart and an even greater incidence of sclerotic changes in the heart muscle, the result of thrombosis and infarction, were found. Cases which had a history of anginal attacks showed greater pathologic changes than those which did not have anginal symptoms. Narrowing of the lumen was found in 22 per cent of the cases presenting anginal attacks and in only 5 per cent of the remaining material. Coronary occlusion was found in 30 per cent of cases of stenocardia and in only 4.6 per cent of the remaining cases. Of all occlusions, 82.4 per cent involved the left coronary artery. Of these, 75 per cent were in the anterior descending branch. In six cases of thrombosis of the right coronary artery, myelomalacia was found four times in the left ventricle and not in the right. The author concludes that occlusion as well as narrowing of the coronary arteries bears a definite relation to angina pectoris. Sufficient evidence, however, does not exist to justify the belief of adherents of the coronary theory that the organic or functional narrowing or occlusion of coronary arteries is the direct cause of an attack of angina pectoris. That narrowing or occlusion of coronary arteries does not always cause attacks of angina pectoris is abundantly proved by postmortem studies. In the author's material, anginal symptoms were present in only eleven of thirty-four cases of coronary stenosis and in fifteen of thirty-six cases of coronary occlusion. A sudden ischemia the result of infarction of the heart muscle, does not always cause pain. The author cites a case in which the patient was dying within one and one-half hours after the onset of circulatory symptoms not accompanied by anginal pain. Postmortem showed that death was due to coronary thrombosis with infarction and myelomalacia. Thus the coronary theory fails to explain why in some cases changes in the coronary arteries give rise to a painful anginal status while in others they do not. The same objections may be advanced against the aortic theory maintained by the Wenckebach school. The author leans to the theory that spasm of the heart muscle rather than of the coronary artery, is the cause of the painful syndrome. In a special study of the heart muscle in fifty

cases of stenocardia and coronary sclerosis, he found degenerative parenchymatous changes, such as hyaline atrophy and fatty degeneration. A comparative study of the heart muscle of syphilitic patients who exhibited anginal attacks and of syphilitic patients who did not reveal a preponderance of myelomatosis in the former. Thus the well known role of syphilis as an etiologic factor in angina pectoris appears to be due to the pathologic process induced by it in the heart muscle. Irregularity in the sclerosing process of the coronary artery leads to irregularly distributed focal lesions in the myocardium. These may lead to focal functional disturbance of conductivity or irritability, to disturbance of coordination of the cardiac components and, thus, to local spasmodic contractions the cause of painful sensations. Fatty degeneration of the myocardium may be caused by other conditions than coronary sclerosis, namely, by syphilitic virus, by anemia and by infections. Since the work of Leriche and that of Pletnev and Khesin, the role of the autonomic nervous system has come to be recognized as another important factor in the pathogenesis of angina pectoris.

Some Experiences with Pyelography—On the basis of about 200 cases of pyelography, Jørgensen concludes that the procedure should consistently be followed in all disorders of the urinary tract and the pyelograms made in the expiratory phase. The ureteral catheter should not be present in the part of the urinary tract undergoing examination. The diagnosis of obstacles depends on (1) the difficulty experienced in bringing the contrast material injected from below past the obstacle and (2) the establishment of retention above the obstacle. Obstacles in the ureter may cause deficient excretion of intravenously introduced contrast substances by the kidneys which shortly before gave abundant diuresis. Improvement of the passage may lead to considerable (life-saving) increase in diuresis. The author affirms that the normal pelvis of the kidney is emptied of the contrast substance dissolved in water, within ten minutes.

Decerebration Rigidity and Gas Metabolism—Hoffmann found that the spontaneous variations in oxygen consumption in decerebrated cats, under fixed conditions of body temperature position and duration of experiments, were within 6 per cent during one hour, with a tendency to continuous rise in some specimens. The carbon dioxide elimination under

the same conditions, varied within 10 per cent in one hour. The respiratory quotient showed a steady decline for hours. The oxygen consumption per kilogram of body weight in the individual specimens did not depend on the degree of hypertension. Extremely rigid specimens sometimes showed relatively low values, and vice versa. Section of the spinal nerves of the musculature of the extremities caused either no change or a slight increase in oxygen consumption.

Esophagobronchial Fistula with Cancer Infiltration in Heart—Hald's patient was a woman, aged 56, who had been operated on for cancer of the uterus in January, 1928, and presented clinical symptoms of the heart and lungs since March 1932. The roentgen diagnosis in September, 1932, was pleuritis on the left side and infiltration of the right lung, and the electrocardiogram showed paroxysmal auricular flutter. In February, 1933, the patient was admitted for treatment with the diagnosis of pulmonary abscess. Roentgen examination now revealed a clarification of two fingerbreadths upward from the hilus and esophageal stricture, with passage of the contrast gruel mainly into the left bronchus and the lung abscess. Witzel's fistula was made for feeding. Death occurred about a month later from heart failure. Necropsy showed the right lung to be large and edematous, the pleura on the left side was totally adherent and the left lung small, with a cavity of the size of an orange partly filled with pus, and total destruction of the surrounding lung tissue. The cavity extended to the hilus, where a broad opening connected with the left bronchus. In the esophageal constriction a large ulceration opened into the left bronchus just above the opening into the lung abscess. The wall of the lung abscess infiltrated the pericardium passing through it into the left auricle, the wall of which was a thick tumor infiltrate. A large papillomatous tumor partly filled the auricle and infiltrated the left pulmonary artery in the hilus. The author considers this a case of cancer metastasis, related to the uterine cancer, with cancer both in the lung and in the lymph nodes. As the left pulmonary artery was stopped only by small, dry thrombus masses the absence of a fatal hemorrhage is regarded as surprising.

Facial Hemiatrophy—Vitiligo—Myxedema—These three disorders developed one after another in a woman, now aged 55, having tardy congenital syphilis presumably cured. Faber sees a close connection between the facial hemiatrophy, which appeared in childhood, and the universal pigmentation anomaly with pigmentation of the face, which set in during the third decade of her life, and ascribes to both a central origin with the starting point in the centers of the sympathetic or autonomic nervous system. The myxedema, which appeared more than twenty years after the vitiligo, seems to him, in view of the close relation between the autonomic nervous system and the endocrine glands, probably not an accidental coincidence but dependent on a deeper, common cause. The hereditary syphilis is thought to have affected the trophic centers as a weakening, predisposing factor, the definite cause of the three disorders being the pronounced psychic disturbances which have influenced the patient throughout her life.

EARLY DIAGNOSIS AND TREATMENT OF CONGENITAL DISLOCATION OF THE HIP

JOSEPH A. FREIBERG, M.D.
CINCINNATI

The early diagnosis of congenital dislocation of the hip is not difficult, even in the hands of physicians inexperienced in orthopedic surgery. It is true that in the normally adipose child it is rather difficult to palpate the femoral head whether it is dislocated or not. On the other hand, there are several signs that should suggest some abnormality about the hip joint and warrant a roentgen examination. After a roentgen examination has been made there should be no question whatever concerning the diagnosis.

In discussing the early diagnosis of dislocation of the hip, the etiologic factors must be considered first. Of the many hypothetic explanations as to why a hip should be dislocated at the time of birth, none seem entirely satisfactory. Excluding the factor of trauma, because of the frequent existence of the deformity in children born of multiparas following normal delivery, an anatomic explanation must be found. There are three anatomic abnormalities existing in varying degrees in all congenital dislocations of the hip: unusual obliquity of the acetabular roof, annular constriction in the abnormally elongated capsule, and anteversion or antetorsion of the femoral neck. The anatomic variations of the superior femoral epiphysis from a roentgen point of view will be discussed later. Of great significance, however, is the constant observation of the fact that the femur itself, though the head is dislocated, is the same length as the corresponding normal femur in a unilateral dislocation. In the infant under 6 months of age, with relatively few exceptions, there has been no occurrence of muscular contractures or compensatory shrinkage of the skin in the leg with the femoral dislocation.

In considering the early diagnosis of congenital dislocation of the hip, the obvious, visible abnormalities play the most important roles. Asymmetrical skin folds in the thigh, though stressed for over twenty-five years in this country,¹ are most frequently overlooked (fig. 1). If the creases on the mesial aspect of the thigh are deeper on one side than on the other, some explanation must be sought. Realizing that at birth and during early infancy there has been no compensation for the

shortening of the distance from the pelvis to the knee, which exists if the hip is dislocated, the soft tissues, skin and muscles, must fold or crease. After the child is 2 years of age, these soft tissue folds are less prominent because the skin and muscles compensate by shortening. In bilateral dislocations of the hip, no asymmetry of skin folds is seen, but abnormally deep folds on both sides may be noted.

Second in importance in the early diagnostic signs is eversion or external rotation of the affected leg. If this external rotation of the leg is noted and abduction is attempted passively, it will be found that this motion is markedly limited. A normal child's leg will abduct passively from 70 to 80 degrees. If abduction is limited to 40 or 50 degrees, some explanation should be sought.

Most deceptive of the early signs of dislocation is shortening of the affected leg. The actual shortening may be so slight that measurement with a tapeline is inconclusive. If, on the other hand, the knees are flexed, and the hips are flexed so that the feet rest evenly on a firm examining table, an inequality in length of the legs becomes apparent. In this position, if one leg is shorter than the other, there will be a definite variation in the level of the knees (fig. 2).

After the preceding signs have been noted, a careful palpation of the hip joint area will elicit further abnormalities. The trochanter on the affected side will feel more prominent laterally, and it will be nearer to the anterior superior spine of the ilium than on the corresponding normal side. If the child is adipose, it may be impossible to palpate the femoral head, but when the leg is rotated the absence of the femoral head beneath the femoral artery in the groin may be noted.

The presence of one or all of these abnormalities of the hip joint and leg should suggest a roentgen examination. In small infants the superior femoral epiphysis may not appear on the roentgenogram, but the break in the normally symmetrical obturator-cavo-femoral line is readily seen (fig. 3). In this country it has become a rule in many of the larger hospitals to have roentgenograms made of all new-born infants to determine the presence of a persisting thymus. In one such hospital all roentgenograms are now taken so that the pelvis and hip joints may be included as well as the thorax. This method of early diagnosis is infallible although it may not be feasible in all instances.

The anatomic variations found in congenital dislocations of the hip are quite constant in character. Whether these variations from the normal are the cause of the dislocations, or the result is a moot question. Suffice it to say, the older the child, the more pronounced do the variations become. Up to 6 months of age, and sometimes until the walking period, the dislocated femoral head lies lateral to the acetabulum and level with the superior margin of the acetabulum. The anatomic variations that are found during this age

From the Department of Orthopedic Surgery, University of Cincinnati College of Medicine.

¹ Freiberg, A. H. The Diagnosis and Treatment of Congenital Displacement of the Hip in Infancy. *Am. Med.* 7: 394-396 (March 5) 1904.

period are confined to the hip joint proper. The acetabular roof, or that portion of the acetabular cavity formed by the ilium is abnormally oblique as compared with the normal hip joint in a unilateral case. As the superior femoral epiphysis does not develop a center of ossification until the child is approximately 5 months of age, a roentgen examination does not elicit abnormalities until this age period.

Fig. 1—Congenital dislocation of right hip before reduction. Slight prominence of right greater trochanter is noted as compared with left. Two deep creases shown on mesial aspect of right thigh and only one crease on left and a slight apparent shortening of right leg. For comparison of legs external rotation of right leg has been corrected.

As the center of ossification of the superior femoral epiphysis develops, in a unilateral dislocation a marked discrepancy in size may be noted by roentgen examination. On the side of the dislocation not only is the ossification center delayed in appearance but also it remains smaller and more irregular in outline. A third important anatomic variation is an inconstant degree of anteversion or anteversion of the femoral neck. Again until the infant is approximately 6 months of age this deformity does not become marked. After weight bearing has begun, however, there is a rapid increase in the anteversion deformity.

Julius Wolff² propounded the theory, accepted almost universally, that bone develops depending on the functional stresses placed on

it. Is a further explanation required for the developmental anomalies seen in congenital dislocations of the hip? In a congenital dislocation of the hip there is an absence of the normal functional stimulation of the acetabulum and the femoral head, and a delayed or pathologic development ensues. On this basis, the earlier the dislocation is reduced, the less severe will the secondary bony abnormalities have become, and the more perfect will be the end-result.

A careful search of the literature, which has become quite voluminous on this subject, will reveal only two reasons why early reductions have not been advocated until recent years. The foremost obstacle to early reduction has been the frequent soiling of the post-operative cast by children who have not yet become cleanly in their habits. The danger of anesthesia in the young infant, and the frequency of fevers and diarrheas of infancy, formidable dangers, to be sure, three decades ago, are no longer important items. It will be found, however, that these were the reasons offered for postponing reductions of congenital dislocations of the hip until the child was 2 years of age.

Up to 6 months of age, the normal infant is essentially a sedentary individual with less acute reactions to its surroundings than the older child. For this reason a method of reduction of congenital hip luxations that requires continual recumbency is not contraindicated. To accomplish a reduction at this age, the femoral head lying lateral to the superior margin of the acetabulum must be brought downward and inward, and rotated. As the femoral head has not been forced upward by

weight bearing, abduction will suffice to bring it downward. By application of plaster casts to the extended legs fastened together by ordinary turnbuckles from a hardware store, all the necessary forces to accomplish reduction may be readily applied (fig. 4).

While the turnbuckles are being incorporated, both legs are held in external rotation. This rotation is then maintained automatically by the two rigid turnbuckles. As gradual abduction is begun, the femoral heads may be forced outward by opening of the upper turnbuckle. When the femoral head has cleared the superior margin of the acetabulum by continued opening of the lower turnbuckle, accompanied by a closing of the upper turnbuckle, as the legs are widely abducted the head is gently forced medially into the acetabulum. In order that the circulation in the legs may be watched closely at all times a narrow wedge of plaster is removed from the entire lateral aspect of the casts. Undue pressure on the soft tissues is easily recognized by a slight blanching of the exposed skin areas. At no time should sufficient force be required to cause the child to be fretful or sleepless. Because the casts need only extend to the midthigh area, the cleanliness of the child may be cared for in the usual manner. If it is desirable to maintain slight traction on the legs during the period of reduction this may be done by placing the child on a slight incline with the head lowered and the lower turnbuckle tied to the foot of the crib. When wide abduction of the legs has been obtained, the upper turnbuckle may be replaced by a cord, so that a simple

Spanish windlass³ to exert constant mesial traction may be used. Once reduction has been accomplished by this method, as proved by roentgen examination it can be maintained simply by leaving the apparatus in place for from two to three months.

Several factors that do not exist in the younger infant must be considered in the treatment of congenital hip luxations in children who have reached the age of 6 months. With occasional exceptions, anteversion or anteversion of the femoral neck has become pronounced when the child has reached the age of 6 months. This is true even though the child has not attempted weight bearing. A normally active child, when awake, is in almost constant motion kicking the legs and waving the arms. If the femoral head lies above and posterior to the acetabulum, the functional bone stimulation caused by motion produces or increases an existing cervical ante-

Fig. 2—Congenital dislocation of right hip. Child is lying on a firm table with knees and hips flexed and with feet together. In this position shortening of leg on side of dislocated hip is readily noted by difference in knee level.

torsion. Likewise, as compensatory shortening of the soft tissues about the hip joint and thigh are well advanced at 6 months of age more vigorous force is required to abduct the legs sufficiently to accomplish reduction. The secondary developmental abnormalities associated with congenital hip dislocations progress rapidly through the second six months of life.

² Wolff Julius. Das Gesetz der Transformation der Knochen. Berlin August Hirschwald 1892.

Until the child is approximately 18 months of age, manipulative reduction of congenital hip luxations is a relatively simple procedure and not associated with severe trauma when correctly carried out according to the method of Paci. For this reason I feel that in children more than 6 months of age manipulative closed reduction under anesthesia should be done. Great force

the bed pan is held firmly in place. The child may then be moved from bed to go-cart, or if desired he may be taken in an automobile. The exposed areas of the cast in the region of the perineum are covered with oiled muslin and require very little attention.

At the end of two months when the first cast is removed and the leg or legs are brought down from complete abduction to 45 degrees of abduction and are internally rotated the "bracket" may be reapplied, as it holds the cast sufficiently high from the bed to prevent pressure on the feet, which are now directed posteriorly.

Open reduction of congenital luxation of the hip is indicated in the very small percentage of cases that cannot be handled satisfactorily by the closed method. Two large series of end-results reported from the continent, including some 5,000 dislocations,³ show that closed reduction is successful in approximately 90 per cent of the cases. It is shown in these reports, furthermore, that the trauma associated with the closed methods of reduction is not an important factor. Lange³ is unable to find evidence that some of the less satisfactory results, even in the older children, may be attributed to the trauma associated with bloodless reduction. Both Putti and Lange found that the reductions done in children up to 3 years of age gave the most satisfactory results.

In the past, the late changes, following reduction, seen in the superior femoral epiphyses have been attributed to the trauma associated with the closed or so-called bloodless reductions. These late changes after reduction, frequently simulating *coxa plana*, or Legg's disease, were found by Lange in equal numbers after the employment of the open and closed methods. Deformities of the femoral head, likewise, have been found in a greater number of congenital luxations of the hip in which reduction has not been attempted. Lange³ also reports three instances in which *coxa plana* has developed in the normal hip joint of children hav-

Fig 3—Congenital dislocation of right hip in a child 10 weeks old. Superior femoral epiphyses have not developed centers of ossification. Lateral and upward displacement of the right hip is easily seen if the obturator-covofemoral lines are compared. A, B, C, D on left side form four points in a symmetrical curve. A', B', C', D' on right side show dissolution of normally symmetrical obturator covofemoral line. External rotation of right femur may be noted also.

is never required in the young child. If gentle pressure does not result in reduction, either the procedure is not being carried out correctly or the case is one of a very few with an unusually firm, small and wide capsular constriction. In a series of cases I have not encountered such a case. In fact, open reduction has been necessary in only one case out of twenty in children under 6 years of age. This was a bilateral congenital dislocation of the hip in which manipulative reduction was successful on one side.

Once the reduction has been satisfactorily carried out and the postoperative cast has been applied, some method is required to prevent soiling of the cast in the young child not yet cleanly in its habits. Free drainage must be allowed. This may be done by placing the child on a Bradford frame, but this necessitates constant recumbency and confinement. Figure 5 illustrates a simple appliance that has been most useful in preventing soiling of the cast. The areas that come in contact with the cast are covered with leather. It is not necessary to fit the "bracket" in each individual case, as a slight discrepancy in size may be accommodated for by loosening or tightening of the leather straps. With the "bracket" applied tightly to the cast, two average sized pillows are placed beneath the head and shoulders of the child. A small bed pan is inserted beneath the buttocks, and the "bracket" is so bent originally that

Fig 4—Ten weeks old child with congenital dislocation of right hip. Two turnbuckles are shown incorporated in plaster casts extending from midthigh area and including feet. Equinovarus deformity of the right foot and calcaneovalgus deformity of the left foot have not yet been treated. Dislocation of the right hip is being reduced by gradual abduction of the legs. This is a case of arthrogryposis.

ing reduced congenital luxations in the other hip. These cases, though few in number, offer further proof that the manipulative reduction in itself is not necessarily the cause of the development of the *coxa plana*.

3 Lange, Max. The End Results of Bloodless Therapy of Congenital Dislocation of the Hip. *Verhandl. d. deutsch. orthop. Gesellsch.* 52: 119, 1929. Putti, V. Congenital Dislocation of the Hip. *Surg., Gynec. & Obst.* 42: 449-452 (April) 1926.

Ludloff⁴ in 1902 stated that the superior femoral epiphysis in a luxated hip prior to reduction was always smaller than in the corresponding hip. This accords with the experience of every one nowadays.

SUMMARY

1 The diagnosis of congenital dislocation of the hip may be made during infancy, before the age of 6 months, by simple methods of observation and examination.

2 Up to the age of 6 months, reduction of congenital dislocation of the hip may be accomplished by gradual abduction of the legs by one of several methods.

3 The original manipulative reduction of Paci is still the most satisfactory method in infants more than 6 months of age.

4 Soiling of the postoperative cast may be prevented, thereby eliminating the principal reason that has been brought forward for deferring reduction until the child is 2 years of age.

5 In infancy, reduction of congenital dislocation of the hip is easily accomplished by closed or manipulative methods. Open reduction is indicated in a very small percentage of cases when closed reduction is unsuccessful.

707 Race Street

ABSTRACT OF DISCUSSION

DR JOHN L. PORTER, EVANSTON, ILL. I believe that the earlier the hip is reduced the less is the danger of distortion and atrophy of the head of the femur. About twelve years ago I operated on a girl, aged 12 years, with a single congenital dislocation. I put her to bed for a month with traction on the leg in order to secure as much lengthening and loosening of the muscles as possible. Dr Lewin and Dr Edwin Ryerson were beside the table when the reduction was performed and we all distinctly heard and saw the head go into the acetabulum. Later I regretted that I had attempted to reduce that hip because the head of the femur was so atrophied and became so badly distorted by subsequent pressure that the patient practically

Fig. 5—An apparatus that may be attached to the plaster cast of a reduced congenital dislocation of the hip. The bracket is constructed of one fourth inch round steel and the areas coming in contact with the plaster cast are covered with leather.

lost most of the motion in the hip. Today I would have turned down a shelf over the head of that femur. I would not even attempt to reduce by open operation a dislocated femoral head in a patient 12 years old. About that time Harry Sherman of San Francisco called attention to the fact that the older

the child and the longer he walks without the head in the acetabulum the greater becomes the atrophy and distortion of the head of femur. The early diagnosis of congenital dislocation of the hip should not be difficult, even in children who have never walked. Dr Freiberg has called attention to the asymmetry of the femoral creases. In my estimation the asymmetry of the gluteal creases is much more distinct and more

Fig. 6—The bracket is so constructed that a small bed pan will fit firmly into it and so that it will rest stably on a level surface. This prevents soiling of the cast by children who are still untrained. The shoulders of the child are supported on ordinary pillows. With this apparatus the child may be taken out either in a buggy or in an automobile.

easily noted even with a child who has never walked. The crux of the whole situation, as regards congenital dislocation of the hip, lies in the education of the pediatrician, the obstetrician and the family physician who happen to have supervision of children during their early months to learn to suspect and take notice of dislocations. In 1929 when Putti first published his article on early reduction of congenital dislocations of the hip, by the same method exactly that Dr Freiberg has discussed, except as to technique, I was impressed with the difficulty of the technique in Dr Putti's method. He abducted the legs with a triangular mattress and then for the triangular mattress substituted a splint which came clear up to the perineum and it was spread apart by an angle. That required continual attention and readjustment of the splint or mattress every time the child's toilet had to be attended to, and it required the constant and everlasting and intelligent supervision of the mother or nurse. I was much impressed with the simplicity of Dr Freiberg's technique with the plaster cast, which comes up only to the middle or upper part of the thigh and does not interfere with the toilet of the child. One turnbuckle can be used to abduct the lower end of the leg and the other one to adduct the other end. The child can be turned over on the stomach. It seems to me to be a very ingenious advance and of great encouragement to undertake reduction at the earliest possible moment.

DR RALPH K. GHORMLEY, Rochester, Minn. My impression is the same as Dr Porter's, that early diagnosis of these cases is becoming more and more important. Certainly nowadays the case seen at the age of 3 or 4 years is considered a very late case, whereas a few years ago it was considered a fairly good average time for reduction. I want to compliment Dr Freiberg on his excellent presentation of what appears to be a simple, adaptable and accurate method.

DR W. P. BLOUNT, Milwaukee. I want to emphasize one point that Dr Freiberg mentioned. It is perhaps the only important thing that has been learned about congenital dislocation of the hip since 1900 when Lorenz summarized the literature in a monograph. It is that the hips have to be reduced early. I have just gone over all the cases of old con-

⁴ Ludloff, Pathogenesis and Therapy of Congenital Dislocation of the Hip. Jena, Gustav Fischer, 1902.

genitally dislocated hips that I have had. I got some of them back as late as eighteen or twenty years after reduction. In reviewing the methods of treatment, nothing seemed to make much difference except the question of how early they were reduced. Considerable mauling of the hip in the early days did not prevent excellent results in a few cases. In others the hips were worse than if nothing had been done in spite of gentle handling. There certainly is a factor that is not understood. I should like to elaborate another point, the matter of roentgen diagnosis. Dr. Freiberg says it is infallible. I would say it is infallible as to the condition of the hip at the time the roentgenogram is taken. It is not infallible in disclosing what has taken place or what will take place.

DR. JOSEPH A. FREIBERG, Cincinnati: I learned yesterday of the death of Dr. Morrison, roentgenologist, in Boston who in November published an article in which he discussed the epiphyses about the hip joint. He emphasized, as he had in a previous paper in 1929, the importance of the superior acetabular epiphysis. This is a small epiphysis which is not apparent on the x-ray film in children under 12 years of age. It is this epiphysis which forms a small projection laterally of the acetabulum, and it is the absence of this epiphysis, in Dr. Morrison's opinion, which causes some dislocations of the hip joint. I don't think that explanation will hold for all cases, but certainly I think it explains certain cases of subluxation which later are apparent as spontaneous reductions of dislocations of the hip. I didn't mention Dr. Putti's splint for early reduction because of lack of time. I devised the cast method to take care of the children when they were sent home. Dr. Blount made one statement which I should like to change slightly. He stated that a great deal hasn't been learned about dislocated hips since Dr. Lorenz's first paper. I should like to add that Dr. Pacis' paper preceded Dr. Lorenz's paper by several years and that he was never given due credit for the manipulative reduction and for his excellent work on dislocated hips.

TREATMENT OF DISEASE OF THE UPPER PART OF THE DIGESTIVE TRACT

PREOPERATIVE AND POSTOPERATIVE

JAMES F. WEIR, M.D.

AND

WALTMAN WALTERS, M.D.

ROCHFESTER, MINN.

The principal lesions of the upper part of the digestive tract for which preoperative and postoperative treatment have been found advantageous are carcinoma of the stomach, benign ulcers of the stomach and duodenum, and obstructions of the biliary tract. The complications associated with the lesions in the stomach and duodenum are penetration or perforation, hemorrhage producing anemia, obstruction leading to starvation, dehydration, hypochloremia, alkalosis and toxemia. Jaundice is a predominant complication of obstruction of the biliary tract, with it are associated varying degrees of hepatic and renal insufficiency, and often hemorrhagic tendencies are present. We shall present here measures which we have found of value in the preoperative and postoperative care of complications that arise in such cases.

PREOPERATIVE TREATMENT OF LESIONS OF THE STOMACH AND DUODENUM

Penetrating Lesions—Patients with penetrating lesions due to ulcer become exhausted from pain, lack of sleep and decreasing intake of food and fluids, these

also lead to loss of weight and dehydration. A similar decline in health occurs more commonly and is more prominent in malignant disease when impairment of appetite and decreasing capacity of the stomach decrease the intake of food and fluid. In many of these cases a few days' rest, plenty of sleep, relief of pain by an approved dietary regimen for ulcer, alkalis, sedatives or occasional laxage will restore waning recuperative power. Filling up the reservoirs of the tissues with fluids, orally, rectally, and occasionally intravenously or subcutaneously, is of decided advantage. If carbohydrate is added either in the diet or as dextrose in the solutions given rectally or intravenously, an adequate store of glycogen in the liver and muscles is assured. Occasionally a large inflammatory lesion, at times palpable, is present. In such case rigid medical care for from ten to fourteen days may cause absorption of the inflammatory products and change the lesion from nonresectable to resectable.

Hemorrhagic Lesions—Anemia, secondary to gross or microscopic hemorrhage, often accompanies these lesions, and the advisability of transfusion must be considered in each case. Opinions differ as to when transfusion should be done if bleeding is acute and severe. Some physicians are guided by the level of hemoglobin content of the blood, others by the falling blood pressure. Some transfuse during active bleeding, whereas others prefer to wait until gross bleeding has ceased. Treatment in each case must be individual. Our practice favors the conservative plan, that is to defer transfusion if possible until after active bleeding has ceased. Then, if the anemia is sufficiently marked, transfusion can be given without much danger of starting bleeding again. If the bleeding is chronic one or two transfusions are given when the concentration of hemoglobin is less than from 30 to 40 per cent. In cases of carcinoma in which anemia is moderately severe, surgical intervention seems to be fairly well tolerated. Furthermore, transfusion frequently does not raise the value for hemoglobin enough to warrant the procedure except in the more severe cases or in those in which the chances of resection of the lesion seem good. Certain authorities state that, if transfusion is being contemplated, it should be done at once. However, in all these cases the blood grouping should be determined so that transfusion can be carried out either immediately or remotely after operation, as seems advisable.

Obstruction—Alleviation of gastric retention with its various manifestations is the chief concern in these cases. Once initiated, this retention tends to persist in the untreated cases. Obstruction leads to vomiting, with a loss of fluids and electrolytes. The chief changes are hypochloremia, alkalosis, dehydration, and increased nonprotein nitrogen in the blood and urine. This condition may progress and lead to tetany, renal insufficiency and death. The loss of electrolytes from the blood and tissues can be accounted for by the loss in emesis and urination. Some authorities believe that these changes account for the symptoms and explain death in cases of obstruction high in the intestine. Similar changes occur if fistulas are present. It has also been shown that administration of solutions of sodium chloride in adequate amounts prevents or controls these changes, but other solutions have little effect. McVicar and Weir¹ have pointed out that the condi-

tion cannot be ascribed to the chemical changes in the blood and that it is dependent on some third factor or series of factors which appears at present to be a primary motor inhibition or ileus.

From the clinical standpoint these changes are noted most commonly in cases of pyloric obstruction, either benign or malignant and either before or after operation. The severity of the changes seems proportional to the degree and duration of the obstruction. The patients seem to tolerate even the higher grade of obstruction fairly satisfactorily for varying lengths of time. Subsequently chemical changes in the blood and toxic symptoms may develop. With the onset of this disturbance, definite hypersecretion appears in the stomach. These changes may occur when the patient is undergoing preoperative treatment, especially if the obstruction is marked. With adequate treatment the chemical disturbances in the blood are corrected and the relation of gastric output to intake is reversed without demonstrable changes in the degree of pyloric obstruction.

Clinically, pyloric obstruction presents varying degrees of loss of strength and weight and dehydration. Although there is no hope or necessity of restoring the patient's weight before operation, an adequate reserve of glycogen protects the body in such a crisis. This is partially accomplished by giving 200 cc of concentrated liquid or semisolid carbohydrate food every two hours. This food is not mechanically or chemically irritating to the stomach. The small amounts do not distend the stomach and retained residue returns readily through the stomach tube.

Dehydration is combated as a routine measure by administration of fluids orally and by proctoclysis, and if necessary intravenously or subcutaneously. The output of urine is carefully watched. This should amount to from 1,000 to 1,500 cc daily and usually requires an intake of fluids of from 2,000 to 3,000 cc daily. If obstruction is marked, dehydration is severe and the fluid intake otherwise is inadequate, we do not hesitate to resort to intravenous administration of 10 per cent dextrose and 1 per cent sodium chloride solution, given from one to three times daily.

Gastric lavage is carried out from one to three times daily, depending on the degree of retention. This not only relieves distress but removes accumulations of food and barium, lessens irritation of the mucosa and aids healing of inflammatory reactions. Tension of the gastric musculature is relieved and its tonus is regained. The patient becomes accustomed to the use of the stomach tube, so that it can be tolerated with less discomfort if lavage is necessary postoperatively. Finally, the stomach is lavaged immediately before operation to lessen the danger of aspiration of regurgitated material into the lungs during anesthesia and the liability of soiling the abdomen during operation.

The blood is examined as a routine to determine the content of chlorides and urea and the carbon dioxide combining power for diagnostic reasons and also as an index of the results of treatment. The frequency of such determinations depends on the presence of any alterations in and the degree of obstruction. If there is evidence of retention of urea, hypochloremia or alkalosis solutions of dextrose and sodium chloride are given promptly in 1 liter doses, two, three or even four times in twenty-four hours depending on the degree of change found in the blood. Such changes can be controlled by adequate treatment, thus restoring the patient to a favorable condition for operation.

Icterus, although rarely seen in such cases, is indicative of severe disturbance of the acid-base mechanism. It is almost always associated with severe alkalosis. The painful spasms can usually be relieved by the administration of 5 cc of 10 per cent solution of calcium chloride with or without sedatives. Treatment should however, be directed at the underlying ileus and changes in the blood, following which relief will be prompt.

As a rule from two to four days of preoperative preparation is sufficient. If the obstruction is severe and the dehydration marked, the time of preparation may be prolonged slightly. However, the obstruction is the fundamental fault and it should be relieved as soon as operation can be done safely. During the preparation the patient should not be kept constantly in bed but should be urged to be up and to move about as much as possible. Muscular and circulatory tonus, pulmonary ventilation and the patient's morale are improved.

POSTOPERATIVE TREATMENT OF LESIONS OF THE STOMACH AND DUODENUM

If toxemia is manifested before operation, close observation should be maintained for signs of its recurrence afterward. It seldom recurs however, and treatment usually readily controls it. The intake and output of fluid should be observed carefully, this is important in any operation but especially in gastric operations. Decreasing urinary output may be the first sign of developing ileus. Lavage is not practiced as a routine but is done if any symptoms develop that suggest possible retention then it is carried out two or three times daily or until the condition is relieved.

Retention after gastro-enterostomy sometimes occurs, usually from the seventh to the fourteenth day after operation. By early recognition and improved methods of treatment, the condition is usually relieved promptly. Treatment consists of lavage and intravenous administration of dextrose and saline solutions and the withholding of food and fluids by mouth. If retention persists in spite of treatment, the abdomen may have to be reopened. A secondary operation such as enteroanastomosis, liberation of adhesions, jejunostomy, or even disconnection of the gastro-enterostomy may be necessary.

The necessity for treatment of the average patient with ulcer recovering from operation is not great. However, regulation of the mode of living and eating, correction of certain habits, and eradication of focal infection seems warranted in many cases. The stomach, handicapped by disease and the temporary trauma of operation should not be insulted by indiscreet eating. We endeavor to avoid engendering functional disturbances in susceptible cases by individual care, and we follow definite indications for any restrictions of diet. Patients who have had mild or vague symptoms of ulcer, whose acidity is normal or subnormal, and who have a tendency to bleed, should in particular have food removed. The young, careless patient or the high-tensioned, nervous man may require constant supervision. In some cases a regimen suitable for the mild ambulatory type of ulcer, with two or three doses of alkalis daily, seems indicated. Although there is no proof that recurrent ulcers have been prevented by such treatment, many observers believe that medical treatment should be rigidly followed subsequent to operation.

PRIOPERATIVE AND POSTOPERATIVE TREATMENT
OF LESIONS OF THE BILIARY TRACT

Jaundice—This is the chief complication of diseases of the biliary tract, liver and pancreas that increases the risk of operative procedures and requires preoperative care. It adds to the seriousness of the condition because of the tendency to hemorrhage and hepatic and renal insufficiency. For several years it has been our custom to hospitalize all jaundiced patients for several days before operation. During this period an effort is made to arrive at an accurate and complete diagnosis of the cause of the jaundice, evaluate the presence or possibilities of complications, prevent or alleviate them, and select the most satisfactory time for operation.

Hemorrhage—The cause of the hemorrhagic tendency in these cases is unknown. It may be latent and detectable only by laboratory tests. In other cases numerous manifestations of bleeding may be noted, and no definite changes may be demonstrable by the usual tests of coagulability of the blood. In an occasional case, thrombocytopenia occurs. There is much evidence to show that this hemorrhagic tendency is an indication of hepatic insufficiency. In the majority of cases the hemorrhagic tendency can be adequately controlled by the administration of calcium salts, solutions of dextrose, and especially by transfusions. It is our practice to give 0.5 Gm. of calcium chloride intravenously daily for three days and to give one or two transfusions to all patients before operation. Occasionally intramuscular injections of whole blood or irradiation of the spleen have been of value. Coagulation tests of the blood are repeated frequently during this treatment. If further development of purpura or prolongation of the coagulation occurs after this treatment, we defer operation. This bleeding phenomenon may occur in cycles, with some tendency to spontaneous remissions. Treatment is continued and operation is undertaken when all factors seem propitious.

Hepatic Insufficiency—This is perhaps the most serious complication in cases of jaundice. Many factors enter into its production, including duration and degree of obstruction, individual tolerance of the patient to jaundice, degree of cholangitis, hepatitis, and biliary cirrhosis. Preoperatively, indications of significant injury to hepatic cells and potential hepatic insufficiency are obtained chiefly from frequent determinations of the serum bilirubin. High levels, fluctuations without change in the degree of obstruction, and the tendency to increase are indicative of injury to hepatic cells. Postoperatively, a slow decline or a rise in the serum content of bilirubin indicates serious or progressive injury to the hepatic parenchyma or failure of its function. Walters and Parham² have pointed out that, if the drainage of bile is pale and thin and its volume has increased, the import is serious and indicates failing hepatic function. We also occasionally encounter severe acidosis, diagnosed chiefly by examinations of the blood. Determinations of bilirubin, urea and carbon dioxide combining power of the blood should be made in all cases in which progress is not satisfactory.

In all these conditions, preoperatively and postoperatively, a high intake of carbohydrates and fluids is the chief recommendation. A high intake of carbohydrates may be accomplished by the use of Karo syrup, honey, candy and the like. In addition, solutions of dextrose are given intravenously freely in doses of 1 liter once

or twice daily. At times this may be increased to 20 per cent strength, 500 cc being given at one dose. There is abundant evidence of the value of this from both the experimental and the clinical standpoint. Our experience strongly confirms the value of such procedures. The patient's preoperative condition is improved, surgical procedures are better tolerated, convalescence is less stormy, and symptoms suggesting beginning hepatic insufficiency can frequently be controlled. Acidosis is combated by sodium bicarbonate, given intravenously if necessary. Sodium chloride and dextrose also are given intravenously. Usually, when the drain is removed from the common bile duct and the fistula closes, marked improvement occurs. During the last two years we have also been giving solutions of sodium lactate in racemic form to some patients with evidence of more severe forms of hepatic injury. This is given on more or less empirical grounds, but occasionally startling results have been obtained.

Renal Insufficiency—This occurs most commonly in cases in which there is evidence of severe hepatic degeneration and is often indicated by abnormal urinary manifestations and a rise of concentration of urea in the blood. Following operation there is often a decreasing flow of bile from the common bile duct and the degree of jaundice may increase. There are progressive signs of uremia. Therapeutically, the chief indication is the use of diuretics. Dextrose in solutions of from 10 to 20 per cent, with or without sodium chloride (1 per cent), fulfils these requirements best.

Biliary Fistula—The organism as a rule tolerates loss of bile satisfactorily even for prolonged periods. Prolonged loss of bile occasionally leads to serious trouble.³ However, not infrequently patients complain of anorexia during the period of drainage of bile externally. This usually disappears when the fistula is allowed to close. Administration of the patient's own bile by duodenal tube may give considerable relief.

In cases of prolonged loss of bile, as in stricture, evidence of hepatic injury may be found by tests of bromsulphalein excretion. Whether this disturbance is due to the loss of bile or to the cholangitis so commonly associated in such cases is uncertain. However, it is known that patients do not tolerate surgical procedures well because of the hepatic disturbance and the often associated hemorrhagic tendency. Adequate preoperative and postoperative care, however, has decreased the risk in these cases materially.

SUMMARY AND CONCLUSIONS

1 Preoperative and postoperative treatment is definitely indicated in the complicated diseases of the upper part of the digestive tract and has markedly lowered the operative mortality and the postoperative morbidity.

2 In the gastroduodenal cases such treatment is important, especially in cases of anemia and obstruction.

3 Obstruction is the most common complication in such cases and requires attention to the stomach locally and to the systemic effects of starvation, dehydration and toxemia. Intravenous saline and dextrose solutions constitute the chief therapeutic weapons.

4 Immediately after operation continued careful observation is necessary in cases of obstruction, with resumption of intravenous medication if any untoward symptoms occur.

³ Wangenstein, O. H. Complete External Biliary Fistula. A Potential Serious Postoperative Complication. J. A. M. A. 93: 1199 (Oct. 19) 1929.

5 In an occasional case in which gastro-enterostomy otherwise is successful, symptoms of retention develop about seven to fourteen days after operation and usually the response to adequate treatment is satisfactory.

6 Subsequent care of the patient with ulcer should be judicious and not engender psychoneurotic tendencies.

7 In cases of jaundice, accurate and complete diagnosis, evaluation of the presence or possibility of hepatic or renal insufficiency or the tendency to hemorrhage, institution of measures for their control and selection of the most opportune time for operation are the chief preoperative indications.

8 A high intake of carbohydrates and fluids and administration of calcium salts, solutions of dextrose and transfusions constitute important therapeutic procedures.

9 Postoperative continuation of these procedures improves the patient's condition, aids in warding off hepatic or renal insufficiency, and shortens convalescence.

10 Frequent chemical examination of the blood before and after operation gives important information as to the course of the disease and the need of more intensive treatment.

ABSTRACT OF DISCUSSION

DR. WALTER L. PALMER, Chicago. In the case of obstructive lesions, a great deal is to be gained by a few days of preoperative treatment. The dehydration and occasional alkalosis may be relieved by the subcutaneous or intravenous administration of fluids containing dextrose and sodium chloride. Frequent gastric lavage removes the stagnant gastric contents, cleans the mucosa, and leaves it in much better condition for surgery. These procedures relieve the distress, improve the patient's sense of well being, allow him to obtain rest and sleep and thereby make him a much better operative risk. It is important to follow closely the daily urinary output during this time and also during the postoperative convalescence. In the cases of massive hemorrhage, my custom with regard to transfusion is quite in accord with that described by the authors. Transfusion is not carried out in the stage of active bleeding unless the blood pressure falls so low and the pulse rises so high that complete exsanguination is feared. With only a moderate drop in blood pressure and a moderate rise in the pulse rate I prefer to delay a day or two until gross bleeding has ceased. Convalescence may be shortened or the patient prepared for operation more rapidly by two or three transfusions over a rather short period of time. Opinions differ greatly as to the need for continued medical treatment after gastro-enterostomy. Regardless of the conflicting statistics on this point, the fact remains that ulcer commonly recurs after gastro-enterostomy. In my experience, recurrent ulcer formation is much more common than is a postoperative dietetic neurosis. I therefore prefer to keep the postoperative patient on a prolonged, moderately strict ulcer regimen in the hope that it may help to protect against a recurrence of the lesion. The crises of jaundice in which a hemorrhagic tendency is present seem to me to be particularly difficult and puzzling. I should like to ask the authors whether or not they have made any determinations of the fibrinogen content of the blood and what success they have in controlling the hemorrhagic tendency, once it has developed.

DR. RUSSELL L. HADEN, Cleveland. The surgeon or the internist in charge needs to know the extent that dehydration can be demonstrated by adequate determination of blood proteins, urine output, the amount of sodium chloride in the plasma, the circulating carbon dioxide in the plasma and the quantity of urea in the blood. The question arises: If there are variations from normal in the constituents of the blood, what is to be done about it? Fortunately all these variations can be relieved for the most part by the administration of simple

solutions of dextrose and sodium chloride. Perhaps the most desirable solution is one containing 10 per cent dextrose and 1 per cent sodium chloride. Patients with marked vomiting and intoxication or intestinal tract obstruction cannot be relieved by a solution of 1 per cent sodium chloride. In such cases I have been using 3 per cent sodium chloride with 10 per cent dextrose and in many instances the sodium chloride content of the solution has been increased to 5 per cent or even 10 per cent. It is interesting that the more concentrated hypertonic solutions of sodium chloride, such as those of 10 per cent, not only relieve the lack of chlorides but also stimulate peristalsis. That is shown beautifully in some of the exhibits Dr. Orr has in the Scientific Exhibits. I am convinced that transfusion is one of the most valuable of all preoperative and postoperative measures, quite aside from its relief of anemia. No one knows just what occurs with transfusion, but the fate of the patient depends on the judicious use of transfusion and on the proper use of certain types of solution.

DR. HORACE W. SOPER, St. Louis. Gastric lavage as usually performed with the ordinary stomach tube often terrifies the patient, produces straining, retching and vomiting and is far inferior to gastric siphonage. I introduce the Levin duodenal catheter immediately into the stomach following operation. The end of the tube is connected by means of a glass tube with the second tube that leads into a bottle on the floor by the bedside. Continuous siphonage of the stomach contents is instituted giving positive information as to the character of the gastric secretion. One can readily determine the presence of hemorrhage, reflux of small intestinal contents and similar conditions. Nausea and vomiting are prevented thus adding much to the patient's comfort. With the tube in place, one can give water early and thirst is assuaged. The nurse frequently disconnects the tube and washes it out with a large glass piston syringe removing excess of mucus and blood clots. The complicated suction apparatus that has been described in the literature for the maintenance of siphonage is not necessary. The objection has been made that siphonage withdraws the essential fluids from the body. As the authors stated, this loss of body fluid is quickly replaced by the employment of intravenous dextrose and saline solutions. In regard to the preparation for operation on the colon, I have found a preliminary course of liquid petrolatum enemata to be of great value. The oil retention enema is given every night for a period of a week or so prior to the operation. The liquid petrolatum, in contradistinction to the cottonseed and other oils used in enemata, inhibits the growth of bacteria, thus adding to the safety of colonic operations. If the time element is important, one should lavage the colon with a 5 per cent solution of sodium sulphate instead of using the usual water, soap-suds or saline solution. As Goldsmith and Dayton showed, the colonic wall is impermeable to the passage of the sulphates, while the saline solutions are readily absorbed.

DR. WALTER W. WALTERS, Rochester, Minn. Two important features in the preoperative preparation of patients with obstructing lesions of the stomach or duodenum are (1) control of the dehydration, toxemia and (2) emptying of the stomach and keeping it free from retained material. Thus the surgeon will have a clean stomach of normal size to work with. In the preparation for operation of patients with obstructive jaundice observation and study in the hospital are of additional value. It enables one to determine whether the jaundice is increasing or decreasing, to estimate the type of obstruction, and to weigh the risk of operation against the risk of delay. One should never hesitate, as Dr. Soper has said, to siphon, not lavage, any retained fluid that may be within the stomach after any surgical procedure. A small tube gently inserted, never does harm. Fluid can be administered by clavis or intravenously to replace that lost by vomiting or by inability to take and absorb fluid through the gastro intestinal tract. Above all, as indexes of the patients' condition are their appearance, the force and rate of the pulse, and the blood pressure. A patient with large degrees of retention usually looks ill, the pulse is usually weak and the blood pressure is lowered. A rapid pulse, or the repeated vomiting of small amounts of fluid subsequent to operation indicates the necessity of passage of a stomach tube. The intake of fluid should always be greater than the output. After operation for obstructive jaun-

since the bile should be carefully observed. Thin, watery bile secreted in greater than normal amounts usually means that the liver is not functioning adequately, and one can sometimes compensate for that in part by administration of dextrose solutions intravenously, and by transfusion of blood. The presence of blood in bile draining from a T tube indicates that the liver is functioning abnormally. It should not be allowed to continue. A continuous drip, introduced into the common duct through the T tube, which had been inserted at the time of operation has had good effect on the bile and on the bleeding. Physiologic solution of sodium chloride or solution of dextrose can be used, and, more recently, we have used solutions of sodium lactate (2 per cent). Whether or not the effect is on the hepatic cell directly, or whether the bile is diluted and drainage is assisted is a question. Whether or not the value for blood urea is rising and whether or not the urinary output is good are indications of the patient's progress after operation.

DR R. R. BEST, Omaha. Dr. Haden spoke of the chemical rights of the patient. I should like to say a word about the mechanical rights of the stomach. I don't believe that any stomach that has been operated on should receive anything by mouth for at least forty-eight hours. This may seem a little radical. I don't believe that the patients should even be allowed to have an ice bag to the abdomen, because of the danger which exists that they might be tempted to commit a gastric indiscretion at this period. I usually see very little distention postoperatively. I am sure a stomach that has been handled by a rubber glove has had more insult to it than one which has had a dietary indiscretion, when bloating usually follows and the treatment is absolute rest, especially in the operative case. Mechanical rest is thus almost insured, and vomiting and distention do not occur. The second point is about the postoperative treatment of operative ulcer cases. I don't believe that these ulcer cases, surgical ulcer cases, belong to the surgeon any longer than they remain in the operating room. After they leave the operating room, such cases should be turned over to the medical colleague with the sincere hope and desire that he will give that patient particular care regarding his diet and medication over a rather long period of time, not just a few weeks postoperatively. A trip to the operating room does not entirely relieve the average patient of his ulcer syndrome.

DR A. L. LEVIN, New Orleans. I wish to emphasize a point. When upper abdominal distention develops postoperatively, the most suitable remedy for that condition is a gastric lavage instead of hot stupes. In 1921 I designed the Levin gastroduodenal catheter to be introduced through the nose. Its introduction is very simple and does not entail hardships on the patient. It is left in place for constant drainage as long as reverse peristalsis exists and duodenal contents are being gushed into the gastric cavity. The relief from this simple procedure is often instantaneous. I wish to call attention to a physiologic point of procedure. When the stomach has been emptied of its duodenal contents, dilute hydrochloric acid, 30 minims (2 cc) in 2 ounces (60 cc) of water, is introduced and the tube is clamped for one hour. This is repeated every two hours, preceded by a gastric lavage with plain water and not a sodium bicarbonate solution. The object is to close the pyloric sphincter, and this can be accomplished only by acidifying the gastric contents and not by alkalization.

DR FRANK SMITHIES, Chicago. One reason why certain surgeons get excellent results in abdominal surgery is that they give their competent internist-associate sufficient time for studying and treating patients before they operate. I will mention several simple features of preoperative preparation. First the twenty-four-hour urine. In how many clinics is it customary to test for albumin by the potassium ferrocyanide method? The nitric acid test usually is made. It takes very little excess nitric acid to convert albumin present into a soluble albuminate and in such circumstances a 'negative' test is reported. Second. How often are casts looked for by dark field? If not so looked for, granular casts often are missed. Third. How many times is a so-called normal blood count considered in relationship to total blood volume? Practically, the patient may have a 'normal blood count' as to red cells, white cells and probably hemoglobin but his blood volume may have been greatly reduced as a result of dehydration. The blood cellular ele-

ments should be estimated in relation to blood volume if one is to avoid false conceptions of these elements as working units, especially when, after operation, total blood volume is increased by intravenous (or by other routes) exhibition of fluids. In operations on the duodenum or the stomach I lavage patients on the table after operation and then siphon out all fluid present or introduced. Transfusion of anemic or shocked patients is done on the table, usually after operation, from 600 to 900 cc of whole blood being given. Furthermore, transfusion of patients who are bleeding as often as is necessary is done with whole blood. I do not wait long to see whether or not hemorrhage is going to cease but, if in spite of two or even four transfusions in twenty-four hours the patient still has a fall in blood pressure and hemoglobin, and an increase in pulse rate, I feel that that patient probably has a 'spurter'. This needs prompt surgical intervention and not waiting until the patient is exsanguinated. So-called liver insufficiency following operations is frequently not 'liver insufficiency' at all. Many of those instances in which the patient "simply melts away before your eyes" and is assumed to have 'hepatic insufficiency' and dies on the fourth day are instances of failure of the suprarenals. In these instances, in addition to solutions of salt, dextrose and the like, pancreatic substance and epinephrine should be administered early and freely, combined with lavage of the upper jejunum.

EXPERIMENTAL ASPECT OF FIXED ERUPTION DUE TO ALURATE, A COMPOUND OF ALLONAL

ADOLPH B. LOVEMAN, M.D.

Instructor in Dermatology and Syphilology, University of
Michigan Medical School
ANN ARBOR, MICH.

In 1903, Fischer and von Mering¹ described the barbituric acid hypnotic diethylbarbituric acid (diethyl malonyl urea), introduced as Veronal. This is now official in the United States Pharmacopeia X as barbital. There were also introduced the sodium salts of barbital under the proprietary names Medinal and Veronal Sodium. Some years later a second derivative of the series was announced, in this, one of the ethyl groups was displaced by a phenyl group. This derivative, phenylethylbarbituric acid, was the proprietary designated as Luminal, the same substance is now official under the name phenobarbital.

In the meantime, numerous hypnotics of the barbituric acid series² in which the ethyl groups are replaced by other alkyl or aryl radicals have been developed, including, among the more common ones, amytal (isomylethylbarbituric acid), dial (diallylbarbituric acid), neonal (N-butylethylbarbituric acid), nostal (isopropyl bromallyl barbituric acid) and pentobarbital sodium.

In February, 1922, Allonal (Numal) was introduced to the medical profession, its special claims being that it contained a very high lipid coefficient, barbiturate (allylisopropyl barbituric acid), thus making it a most efficient hypnotic, and in addition a most effective analgesic because of its association with amidopyrine. In 1927, Elur Alurate was introduced, and in 1932 Alurate Injectable for intravenous or intramuscular therapy was developed. (These do not contain amido-

pyrimine) There is also an alurate tablet on the market which has made its appearance recently

CHEMISTRY AND PHARMACOLOGY

Allonal is a mixture of three parts of allylisopropyl barbituric acid to five parts of amidopyrimine (pyrimidon). This is the proportion present in each allonal tablet, which contains exactly 1 gram (0.065 Gm.) of the former with $1\frac{2}{3}$ grams (0.11 Gm.) of the latter. The trade name for allylisopropyl barbituric acid is Alurate, and in our further discussions this nomenclature will be employed.

Barbituric acid

Allylisopropyl barbituric acid (Alurate)

Pyrimidon

Reinert³ has been able to recover from the urine from 13 to 16 per cent of the alurate given to dogs. He found that most of this was excreted the first twenty-four hours and that he was no longer able to detect further quantities after three days. He compared this excretion with phenobarbital and barbital and concluded that the alurate was destroyed in the body more quickly and that the effect did not last as long as with either of the other drugs.

Cutaneous reactions from the barbiturates are relatively common, but fixed eruptions from these drugs are rare, although they have been reported or referred to by Wise and Parkhurst,⁴ Fowlkes, Goldenberg and Rosen,⁵ Ormsby⁶ and others. It is of interest to note that in Menninger's⁷ review of forty-one cases of skin eruptions from phenobarbital, with a report of three additional cases, there is no mention of the occurrence of any fixed eruptions, although two cases were mentioned as leaving hyperpigmentation.

Unger⁸ reported a case of cutaneous hypersensitivity to amidopyrimine in which the amidopyrimine was ingested in an allonal tablet. The patient experienced marked swelling of the eyelids, cheeks and lips, as well as blotches on the forehead, and the palms and the backs of the hands, accompanied by a generalized fatigue. These symptoms recurred on ingestion of an amidopyrimine tablet. Unger cites Crohn's¹⁰ case in which Crohn had recurrent attacks of urticaria and scrotal and genital edema on taking each of three proprietary barbituric acid preparations. One of the drugs was Allonal, which is chemically similar to Allonal. All three preparations, however, had several radicals in common and the exact cause of the idiosyncrasy was never proved, although Crohn himself believed the

phenyl or antipyrine group to be the offending agent. These two cases are the only two found in an extensive review of the literature on allonal and alurate cutaneous hypersensitivity. Somnifene contains diethylbarbituric acid (barbital) and allylisopropyl barbituric acid (alurate). Few cases of cutaneous reactions have been reported following its administration. However, in no case has it been proved that alurate was the cause of the reaction and in most cases more than one type of barbiturate had been taken.

The following experimental data concerning fixed eruption due to the alurate in allonal, made possible by the remarkable cooperation of our patient, are herewith reported.

REPORT OF A CASE

History.—F. M., a man aged 42, seen in the department of dermatology and syphilology, Nov. 10, 1932, complained of a lesion on the right hip. About three and a half years previously he had noticed two reddened areas on the right buttock. The lesions were moderately itchy and would remain so for three or four days after which they would no longer itch and would subside leaving pigmented areas which have never entirely disappeared. Similar attacks have occurred every three to six months and always in the same areas. No new lesions have ever been noticed. Each exacerbation would last three or four days and then fade. About one year before, the patient stated the lesions began taking on a stippled appearance. For the past four years the patient has had rather severe headaches and admitted taking three or four allonal tablets for relief. He stated that the two areas on the buttock would flare up each time he had a severe headache. He had taken no cathartic medicines and did not remember taking any other form of medication. For the eruption he had had only local therapy.

The patient had always been in good health and nothing in the past history was of significance. There were no unusual idiosyncrasies except that the patient used to have recurrent attacks from ray poisoning.

The family history likewise did not reveal any allergic tendencies.

Examination.—The patient was well nourished and well developed with an eruption on the right hip, posterior and a little inferior to the greater trochanter (fig. 1). This presented as two lesions, one the size of a fifty-cent piece (30 cm. in diameter) and the other nearly twice this size. Both of the lesions were sharply limited and were a peculiar purplish red, the borders of which were raised and the central portion of which presented areas of normal skin. These normal areas gave to the two lesions a stippled or mottled appearance. On palpation the borders and raised central areas were firm and slightly indurated.

A clinical diagnosis of dermatitis medicamentosa was made.

Laboratory examinations revealed nothing of significance. The Kahn test was negative. Examinations of the urine for albumin, sugar and phenolphthalein were repeatedly negative. Examination of the blood showed hemoglobin, 92 per cent; red cells, 4,750,000, and white cells, 6,250. The differential smear was normal. The blood examination was made during a remission.

EXPERIMENTAL DATA

Reproducing the Eruption.—After all signs of activity had disappeared from the two lesions only residual pigmentation being left, three 5 gram (0.3 Gm.) tablets of amidopyrimine were administered (the patient's usual dose). At the end of three days there was no exacerbation of the involved areas and four (the patient's usual dose) allonal tablets were taken by the patient at bedtime. The following morning on arising the patient complained of itching of the two areas on the buttock, and on examination the areas were seen to be similar in every detail to that when first examined in the clinic. It was felt that perhaps the three day interval between the drugs was too short so the experiment was repeated twelve days being allowed to elapse between the administration of the drugs. The results were the same in that there was a definite flare up in the pigmented areas. The result of this experiment showed that amidopyrimine failed to produce the eruption but that exacerbation definitely followed the administration of allonal.

Alurate Since alurate (allylisopropyl barbituric acid) is the only component of allonal that is not contained in pyramidon, it was decided to test the patient to this drug. He was given two 1 gram (006 Gm.) alurate tablets at 9 45 a m and at noon and was aware of slight itching and erythema. At 4 p m he was reexamined in the clinic at which time there was noted a definite exacerbation of the eruption in the two previously active areas on the right buttock.

In order to rule out the possibility of any inert substance used in the manufacturing of the drugs producing the eruption, some chemically pure sodium alurate was furnished by Hoffmann-LaRoche, Inc. for administration. The patient was given 2 grams (013 Gm.) of this drug and reacted promptly with an exacerbation.

Effect of Other Barbiturates After all signs of activity had disappeared from the areas involved, the patient was given 0.2 Gm. of barbituric acid with negative results. Twenty-four hours later this dose was doubled and again administered, likewise with no cutaneous response. At intervals of from forty-eight to seventy-two hours the following drugs were given: barbital (0.65 Gm.), phenobarbital (0.97 Gm.), ipral (calcium ethylisopropylbarbiturate 0.26 Gm.) sandoptol (isobutylallyl barbituric acid 0.4 Gm.) and drial (diethylbarbituric acid 0.1 Gm.). In no case was there any cutaneous manifestation following ingestion of the drug.

Effect of Allylisopropyl acetyl carbamide (Sedormid) As it was thought that possibly the allylisopropyl group per se was the offending agent three Sedormid tablets were administered (0.26 Gm. each) to the patient with negative results.

Effect of Other Drugs Producing Fixed Eruptions Phenolphthalein, antipyrine, amidopyrine and neoarsphenamine are four drugs that in susceptible persons are prone to produce a fixed eruption. The patient had already been tested to amidopyrine with negative results so tests with some of the other drugs were carried out. The patient was given 0.97 Gm. of antipyrine and there was no reaction in forty-eight hours. He was next given 0.16 Gm. of phenolphthalein with no reaction. Neoarsphenamine was not given. This experiment corroborates the work of Novy¹¹ in connection with phenolphthalein.

Fig 1—Localized fixed eruption due to the alurate in allonal

namely that idiosyncrasy for one drug producing a fixed eruption does not necessarily indicate susceptibility to the whole group.

Local Cutaneous Tests—Patch Tests In order to help determine the site of the hypersensitivity in fixed eruptions

patch tests were carried out on both normal skin and the residual pigmented areas on the right buttock. The following drugs were applied to the normal skin and were all negative after ninety-six hours: barbituric acid, phenobarbital, barbital, amyral, amidopyrine, antipyrine and alurate. As the experi-

Fig 2—Residual pigmentation three weeks after injection of allonal

ments were consuming much of the patient's time only phenobarbital, barbital, allonal and alurate were tested on the pigmented areas. There were definite reactions to both allonal and alurate within twelve hours, similar in detail to the eruption produced by ingestion except that it was limited to the contact area (fig 3). Phenobarbital and barbital brought forth no cutaneous response.

Intradermal Tests Normal and pigmented areas were tested with 0.1 cc. of a 1 per cent solution of the following drugs: barbituric acid, barbital, phenobarbital, allonal and alurate. All tests were negative in the normal skin areas but there were definite reactions in the pigmented spots to both allonal and alurate. These reactions reached their maximum intensity in half an hour and had practically entirely disappeared within twenty-four hours.

Scratch Tests Percutaneous tests were performed with the following drugs: barbituric acid, phenobarbital, barbital, allonal and alurate. These tests were likewise performed on both normal and pigmented skin areas. All tests were negative in the normal skin areas, but there were definite reactions in the pigmented spots to both allonal and alurate. The results obtained by this method of testing were not as clear cut and as satisfactory as those obtained by either of the other methods.

Attempts at Passive Transfer—In an attempt to determine passive transferability 0.1 cc. of the patient's serum was injected into each of four persons. In two of these subjects, 0.1 cc. of a 1 per cent solution of alurate was injected into the local site at the end of twenty-four hours. In the other two, intracutaneous and patch tests were done on the area into which the patient's serum had previously been injected. The subjects were examined at frequent intervals for forty-eight hours and in no case was passive transfer of hypersensitivity successful.

Auto-Interchangeable Skin Transplants from Pigmented to Normal Skin—In 1930, Naegeli, de Quervain and Stalder¹² performed a most interesting experiment on a patient with a fixed eruption due to antipyrine. They transplanted a portion of the sensitive pigmented

¹¹ Novy F. G. Jr. Phenolphthalein Eruption. Experimental Data on Its Causation. Arch. Dermat. & Syph. 26: 125-130 (July) 1932.

¹² Naegeli Oscar, de Quervain F. and Stalder W. Nachweis des cellularen Sitzes der Allergie beim fixen Antipyrin Exanthem. Klin. Wchnschr. 9: 924-928 (May 17) 1930.

area to an area of normal skin and transplanted the piece of normal skin to the original pigmented sensitive area. At the end of three weeks the graft had taken nicely, and antipyrine was again given by mouth. There was a flare up in the pigmented transplant to the normal skin area, whereas the normal skin transplanted to the original sensitive area showed no reaction.

Wise and Sulzberger¹³ have recently repeated these investigations in a case of phenolphthalein fixed eruption. Their results were diametrically opposite to those of Naegeli. Similar experiments along the lines outlined by Naegeli were carried out as follows:

The skin was first cleansed with alcohol and iodine. The sites for removal of the tissue were marked with a heavy cross of iodine, which was later removed with alcohol. A local anesthesia was then infiltrated around this area—not into it. Two 6 mm. cutaneous punches were used and areas punched out to a depth of from 3 to 5 mm. These were snipped off smoothly with a scalpel and interchanged immediately, the one from the pigmented area being placed into the depression left in the normal skin area and vice versa. Four per cent xero-

Fig. 3—The lower darker area shows a positive patch test to alurate.

form (bismuth tribromphenate) impregnated sterile gauze was next applied, which was covered with a large bandage held firm by large strips of adhesive plaster. The patient was ambulatory and was allowed all privileges except bathing. At the end of five days the two areas were dressed and a sterile small bandage was applied. The superficial epidermis sloughed from portions of both areas, but at the end of four weeks the "grafts" had healed nicely. At the end of four and again at seven weeks the offending drug was administered. The result was directly opposite to that reported by Naegeli. The normal epidermis transplanted to the sensitive "soil" reacted, whereas the previously sensitive skin, which had been transplanted to the opposite normal buttock, showed no reaction.

This result parallels that of Wise and Sulzberger, but it should be emphasized that the grafts taken by these investigators as well as the ones here reported were deeper than those used by Naegeli and his co-workers. I agree with the former that the results of these experiments bring no proof that the epidermis or superficial cutis (or both) is the "shock site" and

seem rather to favor a theory of regional hypersensitivity dependent on deeper structures (nerves and blood vessels). However, I am unable to reconcile my positive patch tests exclusively with such a view. The experiments require further investigations, and it is suggested that in any future work larger full thickness grafts be used in order that the results may be more visible—especially since portions of the transplants are very likely to slough off. Since scar tissue may result from transplants, it would be worth while to allow the wound to heal by secondary intention and compare the results.

SUMMARY

A patient had an eruption which was clinically due to some drug. Exacerbation of the eruption was produced by the suspected drug, namely, allonal. As allonal contains both alurate and amidopyrine, these were administered separately in order to determine the offending agent. The patient reacted to alurate but showed no cutaneous sensitivity to amidopyrine. In order to rule out the "allylisopropyl" radical of allonal as the offending agent, this constituent was administered in the form of allylisopropyl acetyl carbamide, with negative results. Impurities in the drug as a possible causative factor were ruled out by the positive result following administration of pure sodium alurate. Numerous other barbiturates were administered with impunity. Other drugs producing fixed eruptions, namely, phenolphthalein, antipyrine and amidopyrine, had no effect in this case. Attempts at passive transfer were unsuccessful. Patch, intracutaneous and scratch tests were performed with allonal and alurate, as well as with numerous other barbiturates.

Autogenous skin transplants were done the results of which corroborated those of Wise and Sulzberger but were opposite to those of Naegeli, de Quervain and Strider.

CONCLUSIONS

- 1 Fixed eruptions similar to those produced by phenolphthalein may be produced by alurate (the barbituric acid component of allonal).
- 2 Cutaneous hypersensitivity to one barbiturate does not necessarily preclude sensitivity to other members of the group.
- 3 Sensitization to alurate in the case studied existed as a unique phenomenon and did not include sensitivity to other drugs known to produce fixed eruptions.
- 4 Patch, intracutaneous and scratch tests were all positive to allonal and alurate in previously active areas but produced no reaction in normal skin areas.
- 5 Normal skin transplanted to the previously active areas flared up with readministration of the drug, whereas previously reacting skin when transplanted to normal skin areas, did not react.

ABSTRACT OF DISCUSSION

DR. SAMUEL M. PECK, New York. The only basis for assuming that fixed drug eruptions are of an allergic nature lies in the fact that this type of eruption has been definitely proved to be based on idiosyncrasy. Skin tests are usually negative, both patch and scratch, and in the majority of instances antibodies have not been demonstrated. Any experiment, therefore, that throws more light on the pathogenesis of these eruptions is important. The specificity of the idiosyncrasy in Dr. Loveman's cases is especially interesting because of the work I have been doing with nirvanol. When 3 Gm. of the ordinary commercial product was given in about ten days in thirty-seven cases of epilepsy and chorea, a drug eruption developed in twenty-seven. The eruptions resembled serum sickness in many particulars. It came on in about ten days

¹³ Wise, Fred and Sulzberger, Marion. Drug Eruptions. I. Fixed Phenolphthalein Eruptions. *Arch. Dermat. & Syph.* 27: 549-568 (April) 1933.

after the first dose of the drug and when the eruption had subsided the patient usually remained sensitized so that a small amount of the drug given a month or more later could provoke the eruption. I was able to show that the commercial product was racemic in nature and I was able to split it into dextro and levo miranol. Tests on various animals show that the levo substance is 15 times as strong as the dextro substance both as to minimum effective dose and as to minimum lethal dose. The incidence of miranol disease was 28 per cent in a series of eighteen children who received an average of 28 Gm during a course of from eight to ten days. The incidence of miranol disease with the levo form was 64.5 per cent (series of fourteen cases) in spite of the smaller dosage. It is very difficult to understand why Dr Loveman was able to get positive scratch tests in his cases. Usually positive scratch tests apply to the urticarial type of lesions. I think too that instead of calling his tests patch tests he should call them Moro tests because of the analogy to the Moro type of tuberculin reaction. The results of the experiments of Naegeli and his collaborators seem to demonstrate that the antibodies in fixed drug eruptions were bound to the epidermal and perhaps the immediate subepidermal structures at the site of the eruption. It has not been possible for either Wise and Sulzberger or Loveman to confirm this. I think however, that positive experiments like Naegeli's merit consideration.

DR MARION B SULZBERGER New York. It is naturally gratifying to Dr Wise and to me that the author's transplant experiments turned out in the same way that ours did. I do not think that the difference in the experience of Naegeli, de Quervain and Stalder and those of Wise and myself, can be explained by the fact that our grafts were deeper than those made by Naegeli and his associates who took Thiersch grafts. Wise and I had a full thickness graft almost 30 mm in diameter and we could be sure that the major portion of the original epidermis was there and that it had not sloughed off. If in our case the sensitivity had resided and remained in the epidermis and could have been transferred with that tissue we should have accomplished it with our method. This was not a negative experiment only but also a positive one for when we took a previously unaffected full thickness skin graft and transferred it to a previously affected area we did get a positive result previously unaffected skin became sensitized when it was transplanted to a hypersensitive area. This observation suggests that the transplant has become sensitized and that the forces governing this sensitization probably originate below the thickness of our graft. This opinion is corroborated by the fact that in the histologic examination of phenolphthalein eruptions I have found vascular changes deeper down than is ordinarily believed. My hypothesis receives further support from the shape of the lesions in fixed eruptions. If one thinks of a small terminal artery or nerve as a tree with more or less symmetrically branching terminals, a section across these terminals at skin level would assume the round oval or irregular but sharply demarcated form of most fixed drug eruptions. Considering all factors it is probable, in Dr Loveman's case and in ours that the specific sensitization to the drug is dependent on a nerve or a blood vessel supplying the area that has become sensitized. As Dr Highman has so aptly pointed out this is a question of fundamental significance. The author's case seems to substantiate ours. However it seems to me possible that Dr Loveman's results were different from those of Naegeli and his co workers because the original epidermis did not survive in the healed transplants (the transplants were too small to be sure of this). Before reaching a conclusion in a matter of such importance I should like to see more experiments of this kind with large full thickness transplants. Only then would I be willing to regard our results as proof of a general and underlying principle regarding the role of the nerves and blood vessels in determining areas of fixed drug hypersensitivity.

DR JAMES HERBERT MITCHELL Chicago. Did this patient who was getting relatively large doses show any signs of catharsis? Three weeks ago a patient of mine who had been under observation for many years came in to tell me that he feared he was developing a cancer. He had catharsis each

morning, which disappeared about noon time. On investigation I found he had been taking six allonal tablets every night. I advised him to stop the allonal. He called me up yesterday to tell me that he had had no further catharsis.

DR WALTER J HIGHMAN, New York. This interesting paper recalls one read in Havana by Dr Wise, with whom Dr Sulzberger has collaborated. Quite apart from the technical data in Dr Loveman's work the remote implications of his work may throw light on the obscure question of localization of skin lesions due to systemic disturbances, as the so called disseminated lupus erythematosus. If the principles implicit in this paper and in that of Wise and Sulzberger of last year are applied to dermatoses of the type I have just mentioned, a beginning may be made toward clearing up the important problems of localization.

DR W U RUTLEDGE Louisville Ky. A patient of mine a woman had a macular solitary scaling patch on the left buttock about 30 mm in diameter which appeared periodically. For some time I had tried to find out the cause. I tried to associate it with some article of clothing she was wearing but finally elicited the fact that at night she took two or three teaspoonfuls of elixir of medinal every now and then and each time following the medication the area would flare up then exfoliate and subside. After talking to Dr Loveman, I told her to substitute a tablet of allonal for the medinal but this did not cause the eruption. Since she stopped taking medinal the area has become a smooth slightly pigmented spot.

DR GEORGE MILLER MCKEE, New York. Loveman's carefully executed work appears to corroborate the belief that sensitization may occur at various levels in the skin. Thus one may obtain a positive patch test and a negative scratch or intradermal test or vice versa. Positive patch tests are obtained in dermatitis venenata, positive scratch tests are seen in neurodermatitis disseminata positive intradermal tests are obtained in some types of dermatophytosis, and so on. Fixed phenolphthalein eruptions are likely to give a positive intradermal test while the eczematoid type of phenolphthalein eruption may give a positive patch test. When the so called shock center is in the skin, it may be in association with either the deep or the superficial vessels. This may possibly explain the discrepancy in the results of transplant experiments made by the Germans as compared with those made by Wise and Sulzberger and by Loveman.

DR ADOLPH B LOVEMAN Ann Arbor, Mich. I wish to thank Dr Peck for his suggestion about not calling the tests contacts or patch tests. I felt rather reluctant about this myself, so about four days ago I decided to perform a patch test on the transplants. I had not done this before, but I am glad to report that the results were the same as those produced by ingestion of the drug. The previously normal skin transplanted to a previously reacting soil reacted whereas the previously affected skin did not react when transplanted to a normal skin area. I wish also to thank Dr Sulzberger for his discussion and to assure him that the patient is still cooperating and willing to do so in the future. To Dr Mitchell I wish to say that on the contrary, the allonal produced constipation in my patient rather than catharsis. I am sure that following Dr Highman's remarks there will be a number of papers in the near future dealing with autogenous skin transplants in various dermatoses, especially psoriasis. I am glad that Dr Rutledge tried allonal in his case for it helps to bear out my conclusion that sensitivity to one barbiturate does not necessarily indicate sensitivity to other barbituric preparations.

Simple Sewing—Benedict studied a group of women in a large respiration chamber and determined the increase found in ordinary occupations. When they were standing their metabolism was 9 per cent above the basal simple sewing increased heat production 13 per cent dusting 134 per cent sweeping 150 per cent. He found that when a woman climbed an average flight of stairs she expended two calories. For the same expenditure of energy she could walk down three flights of stairs or could walk about 45 yards on the level.—Du Bois, E. F. Total Energy Exchange in Relation to Clinical Medicine *Bull New York Acad Med* 9:680 (Dec) 1933.

THE EFFECT OF PREGNANCY ON
THE URINARY TRACT

HARRY P. LEL, MD

AND

WILLIAM F. MENGERT, MD

IOWA CITY

Pregnancy causes definite and marked changes in the urinary tract. The most striking change consists of a dilatation of the ureter and kidney pelvis, usually more marked on the right side, this phenomenon is so common that it might well be said to be a normal concomitant of the pregnant state.

Probably the most widely recognized articles on the urinary tract of pregnancy are the papers by Hofbauer¹ and by Duncan and Seng² published in 1928. Hofbauer, working on ureters taken from women dying during pregnancy, showed by histologic methods that there was hypertrophy and hyperplasia of muscle and fibrous tissue of the ureter and the perireteral sheath, the greatest change taking place in the lower portion of the ureter, and from this he reasoned that there was produced an obstructive process which would account for the ureteral dilatation. Dugald Baird³ recently has confirmed this finding but states that the amount of hypertrophy and hyperplasia does not always correspond to the amount of dilatation present and that, regardless of the greater dilatation taking place on the right side the degree of hypertrophy and hyperplasia is the same in both ureters.

Duncan and Seng by means of cystoscopy and retrograde urography during all stages of pregnancy, and from the ninth to the twenty-fifth day post partum found that there was dilatation of the right ureter and kidney pelvis in all cases of pregnancy, and of the left ureter and kidney pelvis in 71 per cent of their cases. They found that dilatation began in multiparas as early as the sixth week of pregnancy and in primiparas as early as the tenth week, and that dilatation reached its maximum by the twenty-second week in multiparas and by the twenty-fourth week in primiparas and continued unchanged throughout the remainder of the pregnancy. They apparently were reluctant to perform cystoscopy and retrograde pvelography during the puerperal period, but they did study their patients from the ninth to the twenty-fifth day post partum and found that a majority of their cases showed a return of the urinary tract to the normal, nonpregnant condition by the ninth day. Many of their cases had not returned to normal by the twenty-fifth day and some of their cases showed dilatation of the upper urinary tract for a long time.

With the introduction of intravenous urography, a safe method was presented for studying the urinary tract in pregnancy and especially in the puerperium, or during that period from delivery to the tenth postpartum day. We decided to make such a study. A preliminary report of our results has already been made.⁴

We soon found that others had had the same idea, notably Crabtree and Prather⁵ and Cornell and Warfield⁶ in the United States, Dugald Baird³ in Scotland, Carreras and Figueras⁷ in Spain, and Paul Schumaker⁸ in Germany. All of these found that there was some degree of dilatation of the upper urinary tract in every pregnancy, 100 per cent on the right side and from 70 to 85 per cent on the left, and that the right side tended to be dilated to a greater extent than the left. These conclusions correspond to ours.

In addition we found that the reduction of the urinary tract to the normal nonpregnant condition took place rapidly so that a majority of our cases had returned to normal by the ninth or tenth postpartum day provided the pregnancy, delivery and puerperium had all been normal. We found definite reductions in the dilatation of the upper urinary tract as early as from six to twenty-four hours following delivery, and in some of our cases the urinary tract was apparently normal by the third postpartum day. In those cases in which delivery was complicated, as by forceps or by cesarean section or in which there was postpartum uterine or pelvic infection, the involution of the upper urinary tract was delayed, and in some cases there was even a tendency for the upper urinary tract to return to a dilatation as great as or greater than that which had been present during pregnancy.

This constant dilatation of the upper urinary tract in normal pregnant women with its prompt recession after the termination of pregnancy and its tendency to return to the antepartum condition when there is interference with the normal course of the puerperium prompted us to seek the cause for the dilatation. In reviewing the literature we found that various theories had been advanced but that none of them had been proved. The majority of these theories hypothesize the occurrence of obstruction in the lower portion of the ureters. Thus Hofbauer, believing that the hypertrophy and hyperplasia taking place in the ureter and ureteral sheath cause a narrowing of the lumen of the ureter, states that by the actual demonstration of an obstructive process in the lower urinary tract, the fallacy involved in much of the speculation concerning ureteral dilatation during pregnancy is rendered obvious for according to the evidence just adduced, a readily demonstrable anatomical factor stands out in the etiology of the condition.

Duncan and Seng while not agreeing with Hofbauer that there is actual narrowing of the ureteral lumen but believing that these changes are due to normal physiologic processes sum up their article by saying that the factors causing obstruction to the ureters are

- 1 Increased vascularity of the cervix and parametrium producing pressure capacity and congestion
- 2 Pressure from the general overcrowding of the pelvis from the growing uterus developing equally in all dimensions
- 3 Marked congestion and distortion of the vesical trigon
- 4 Dextrorotation of the uterus

Dugald Baird¹⁰ speaks of passing a ureteral catheter by a soft obstruction 10 or 15 cm above the ureteral orifice. He says: "The obstruction is due to increased vascularity and congestion of the cervix and parametrium and to pressure of the uterus in the pelvis as a result of growth of the uterus which enlarges in all directions." The dextro-rotation of the uterus may cause kinking of the right ureter and explain why

Fig 1—A normal dilated kidney pelvis and ureters in normal pregnancy one week ante partum in a primipara aged 18. B normal puerperium three days post partum showing rapid subsidence of dilatation.

there is nearly always more dilatation and delay on the right side. When the atony of the ureter reaches a certain stage, the mere fact of its falling over the pelvic brim causes its walls to come together and occlude the lumen." Baird³ in a later article states that he has performed cesarean section on women with a rotation of the uterus to the left, yet there was greater dilatation of the right ureter and kidney pelvis.

Crabtree and Prather⁵ state: "From our own observations and the literature now available, we are prepared to accept as a working hypothesis that pelvis and ureteral overdistention exists in all pregnant women as a result of a tight-fitting fetus in an inelastic abdomen. Other factors, such as the course of the ureter over the osseous pelvis, the ligaments of the uterus, fascial layers and the course of important vessels, conspire to produce a difference in degree of dilatation and preponderance of right-sided changes."

Paul Schumaker⁹ states that "the cause of dilatation of the ureter and kidney pelvis is a compression of the hypotonic ureter between the posterior wall of the uterus and the belly of the psoas muscle."

Williams¹⁰ is very definite in saying that pyelitis of pregnancy is due to pressure of the pregnant uterus on the ureters, while De Lee¹¹ states that, since the pregnant uterus has almost the same specific gravity as does the remainder of the abdominal mass, it cannot therefore cause pressure on the ureters.

It is thus seen that obstruction is advanced as the cause of ureteral dilatation, this obstruction resulting from one or more of three principal conditions: (1) actual decrease in the lumen of the lower ureter by hypertrophy and hyperplasia of the tissue of the ureter and periureteral sheath, (2) pressure between the enlarging uterus and the brim of the bony pelvis or the belly of the psoas muscle, and (3) increased vascularity of the structures surrounding the ureter.

Any one who has catheterized the ureters in pregnancy knows that comparatively large catheters may be advanced up the ureter to a point well above the brim of the bony pelvis or the belly of the psoas muscle. Caulk¹² and also Pugh¹³ have advocated draining the ureters in pyelitis of pregnancy with large catheters, and Pugh states that he has had no difficulty in passing sizes 12 and 14 F. We have had no difficulty whatever in passing sizes 8 and 10 F. If pressure from the enlarging uterus were responsible for the dilatation, one would not expect to see dilatation beginning at the sixth to the tenth week, at a time when the uterus is still a pelvic organ, and one would expect to see increasing dilatation as the uterus becomes progressively larger and heavier, instead of the actual finding that dilatation reaches its maximum from the twenty-second to the twenty-fourth week and then remains stationary.

When one views a series of intravenous urograms obtained on pregnant women, one is struck by the fact that there appears to be extremely good filling of the kidney pelvis and upper two thirds of the ureters. The ureters, however, seem to be cut off at a point corresponding to the brim of the bony pelvis and below this point are not visualized, suggesting that there is ureteral obstruction at this point; this is a finding often used as an argument for obstruction.

In order to determine whether or not actual obstruction existed in that portion of the ureter not visualized by intravenous urography, cystoscopy was done on ten pregnant women and ureteral catheters were introduced just beyond the ureteral orifices. Retrograde pyeloureterograms were made in stereo so that the kidney pelvis and entire ureter were visualized on each side, and careful study was made for any evidence of decrease in the size of the normal ureteral lumen, or ureteral constriction that might be produced from extra-ureteral conditions. While these ureterograms show bends in the ureter at about the junction of the lower and middle thirds, with usually marked dilatation above these bends, when they are studied stereoscopically

Fig 2—A normal pregnancy one month ante partum in a nullipara aged 17. B six hours post partum showing contrast of right pelvis and ureter with that in antepartum appearance.

cally it can be seen that these bends are nothing more than curves, without any actual kinking, and that they have no relation to the brim of the bony pelvis. None of these ureters present any evidence to suggest that

there has been a diminution of the ureteral lumen, and there is nothing to suggest pressure on the ureter from surrounding structures.

In our original study we were struck by the rapidity with which involution occurred in the upper urinary tract following parturition. In cases in which we had obtained intravenous urograms from six to twenty-four hours following delivery there was marked decrease in the dilatation of the pelves and ureters. At this early time the cups of the calices were beginning to change

The combined pelvis and ureteral capacity was determined by injecting sterile water to the point of discomfort or very mild pain. A retrograde pyelo-ureterogram was then made with 12 per cent sodium iodide solution injected into the ureter and pelvis to their capacity. This pyelo-ureterogram was compared with the intravenous urogram previously obtained. The catheters were then allowed to remain in situ for ureteral drainage for twenty-four hours. After draining twenty-four hours, the catheter ends were plugged and another intravenous urogram was made, followed by a retrograde pyelo-ureterogram. These pictures were then compared with the ones made the previous day to see if any change had taken place following the ureteral drainage.

There was no difference between the intravenous and retrograde pyelo-ureterograms so far as delineating the size and shape of the ureters and pelves was concerned. The retrograde films, of course, gave the better pictures. Edema could not be discerned about the ureteral orifices. No difficulty whatever was found in passing the ureteral catheters. In most cases the catheters did not pass the full distance to the kidney pelvis meeting with marked curves in the upper

ureter beyond which the catheters could not be passed, but in all cases the ureter was adequately drained. In one case with number 8 catheters 1,125 cc of urine was drained from the right side and 1,240 cc from the left, and after this drainage no urine could be aspirated from either side and the patient had passed no urine from the bladder. In another case, with number 7 catheters, 1,130 cc was drained from the right side

from the rounded, blunted character seen during pregnancy to the sharper more angulated character seen normally, and the width of the ureters had markedly diminished. This suggested that the cause of the dilatation had been removed with the emptying of the uterus.

If dilatation of the upper urinary tract during pregnancy is caused by obstruction in either by the enlarged uterus or by any other condition within the bony pelvis, and if significant reduction in this dilatation occurs in a short time (from six to twenty-four hours) following delivery, as a result of relief of this obstruction, a similar reduction in dilatation should occur if this obstruction can be relieved by any other means. The simplest means of overcoming lower ureteral obstruction is by draining the ureters with ureteral catheters introduced high enough in the ureters to insure their being above any point in the lower ureters where obstruction might occur.

For this study, fifteen women were chosen, all in their last month of pregnancy and all of whom had had normal courses during their pregnancies. Most of them were within a few days of term. An intravenous urogram was first made. Immediately following this, a cystoscope was inserted into the bladder and the ureteral orifices were carefully noted for any edema. A 7 or 8 F whistle tipped ureteral catheter was then inserted up each ureter as far as possible. The residual urine present was measured and a microscopic examination was made on each specimen of urine for pus

Fig 3—A normal pregnancy one week ante partum in a nullipara aged 18. B one day after normal delivery showing size of ureters and kidney pelves. C four days post partum with foul profuse lochial discharge. The patient had a temperature of 103 F. The left ureter and pelvis are larger than they were ante partum.

Fig 4—Lower ureters at term visualized stereoscopically. The marked curves are not points of kinking and no evidence of obstruction can be seen. A nullipara aged 18, B primipara aged 21, C secundipara, aged 18.

and 1,035 cc from the left side and again there was no residual urine in the kidney pelves or ureters on aspiration. None of these cases showed any diminution in the degree of dilatation after such drainage.

A series of intravenous urograms was also obtained on nonpregnant women with various types of pelvic disturbance. It is known that ovarian cysts will produce slight dilatation of the ureters and kidney pelves. This dilatation, however, is not nearly so marked as in

pregnancy In our series we have two cases of ovarian cyst, one tubo-ovarian abscess and one para-ovarian abscess that show slight degrees of dilatation in the upper urinary tract Abscess of the broad ligament, chronic pelvic inflammatory disease, carcinoma of the ovary, dermoid cyst of the ovary, and uterine fibroids failed to show any changes in the upper urinary tract One woman with a pituitary tumor and one female dwarf with glandular dystrophy, probably pituitary, failed to show any changes of the urinary tract

Fig 5—Normal pregnancy one month ante partum in a nullipara aged 19 A before and B after ureters had been drained twenty-four hours to overcome possible obstruction in lower ureters There has been no change in dilatation

In the light of these observations we are very skeptical that ureteral obstruction, from any cause whatever, is the reason for dilatation of the upper urinary tract in pregnancy It seems to us that the condition is the result of some cause inherent in and peculiar to the pregnant state, but what the cause is we are unable to say, and this is a problem that is yet to be solved

CONCLUSIONS

1 Dilatation of the upper urinary tract to some degree occurs in every pregnancy and is a normal concomitant of pregnancy

2 This dilatation subsides rapidly after the termination of pregnancy, provided the pregnancy, delivery and puerperium are normal, and in many cases a marked decrease in the size of the ureters and pelvis can be demonstrated within twenty-four hours following delivery

3 Abnormal delivery or an abnormal puerperium interferes with the return of the upper urinary tract to normal

4 In ten normal pregnant women, retrograde pyeloureterograms failed to show any evidence of obstruction anywhere along the course of the lower ureter

5 In fifteen normal pregnant women, draining the ureters with ureteral catheters for twenty-four hours, in order to overcome any obstruction that might possibly be present in the lower portion of the ureters, produced no change in the degree or character of the dilatation of the upper urinary tract

6 With the exception of ovarian cysts and ovarian abscesses, pathologic conditions in the female pelvis do not cause dilatation of the upper urinary tract

7 Evidence is presented which disproves the theory of lower ureteral obstruction as the cause for dilatation of the upper urinary tract in pregnancy

University Hospitals

ABSTRACT OF DISCUSSION

DR WILLIAM E STEVENS, San Francisco In my experience the majority of cases of pyelitis of pregnancy clear up subjectively after delivery The urine continues to show a few pus cells, however, cultures may or may not be positive, and a low grade infection persists indefinitely unless the patient receives treatment Many patients apparently cured by treatment during pregnancy or after delivery have a recurrence during the next pregnancy notwithstanding the absence of demonstrable pathologic conditions in the urinary tract It is well to remember that a clear urine, microscopically negative as to pus cells, may still be infected Treatment should be continued until the urine is culturally as well as microscopically negative In cases resistant to treatment, search for abnormalities of the urinary tract by means of pyelography, ureterography and cystography is indicated Obstruction and inflammation of the urethra or the ureters should not be overlooked In my experience, about 18 per cent of cases of pyelitis associated with pregnancy first show subjective symptoms during the puerperium These cases have responded better to treatment than cases of pyelitis occurring during pregnancy Compression of the ureter by the uterus shown in two of my pyelograms proves in my opinion that pressure is at least a contributory factor in dilatation of the upper urinary tract Urethral catheterization is inadvisable in urinary stasis without infection unless there is marked dysuria or discomfort, and unless there is a large amount of residual urine I find residual urine in 81 per cent of postpartum bladders One bladder contained a residual urine of 1,020 cc immediately after 750 cc had been voided The importance of the relief and prevention of bladder distention cannot be overemphasized Cases are on record in which the bladder has never regained its tone after labor and operation In my experience, excellent results have been obtained by catheterization of the ureters in pyelitis of pregnancy and by catheterization of the postpartum bladder in the presence of residual urine both with and without infection

DR R M NESBIT, Ann Arbor, Mich Regarding the ascendancy of pyelitis, Dr Helmholtz has laid the ghost of this very effectively In every case of pyelitis of pregnancy the patient should be followed carefully post partum until she returns to normal The excellent work of Crabtree and

Fig 6—A normal pregnancy eight days ante partum in a nullipara aged 23 B one day post partum The decrease in dilatation has occurred in twenty-four hours after delivery

Prather emphasized the fact that the changes in pregnancy which may become more or less permanent should be looked for in every patient who does not have an immediate relief of symptoms and signs following delivery of the child For that reason it is important that this fact be emphasized I have recently studied two cases in which there have been repeated pregnancies The patients were two girls both of whom had three pregnancies, in all of which pyelitis of pregnancy occurred These girls appeared following delivery and both were found to have dilatation of the upper ureteral tract, both

bilateral, with distinct narrowing of the ureter at the parametrium. I could not believe that there had been a stricture until I saw these two patients, both bilateral in one and unilateral in the other. In one the ureter responded well but in the other an operation had to be performed. In all these the obstruction was at the parametrium and not at the bladder wall. If an indwelling catheter is left in place in patients without gross infection the urinary tract will be infected, unless there is gross urinary infection it should not be used.

Dr M. W. SHIRWOOD, Milwaukee. Last year a group of us who went to Iowa City to visit Dr. Alcock were much interested to see the results he was obtaining. Luchs states that the condition favoring an ascending infection in the last months of pregnancy is present in more cases than those in which pyelitis actually occurs, and he believes that the ascending pyelitis of pregnancy is only the infectious stage of the demonstrable changes conditioned by pregnancy. Hofbauer states that dilatation of the ureter and pelvis is physiologic in pregnancy, as so well demonstrated by Lee at the University of Iowa. Secondly he states that a large number of pregnant women have an asymptomatic bacteriuria and thirdly that a high degree of dilatation is accompanied by decreased local resistance. Heaney points out how intestinal infection is caused in the pyelitis of pregnancy and reports a case of severe intestinal infection. In a report from Berlin a patient developed pyelitis of pregnancy and the organism causing food poisoning was recovered. Better meat and food inspection eliminates and prevents pyelitis of pregnancy in many cases. DeLee takes the stand that bacteriuria is found in a large percentage of healthy pregnant women, probably the result of constipation. The ureters, particularly the right ureter, have been found dilated and filled with urine in two thirds of the cases coming to necropsy. Thus, DeLee asserts, is caused by torsion stretching and kinking of the ureters due to enlargement and dislocation of the pelvic organs. Harmacker believes that all pyelitis in pregnancy is due to pressure plus congestion. It seems that all cases of pregnancy are potential cases of pyelitis, the only necessity for completion of the circle being lowered resistance. The treatment advocated by Hofbauer 0.5 cc of solution of pituitary three times a day for two weeks is interesting. He claims there is no interruption of pregnancy. I should like to hear the results of those who have tried it.

Dr. JOHN K. ORMOND, Detroit. In most instances of pyelitis of pregnancy the acute symptoms clear up promptly under alkalization and forced fluids, but a bacteriologic cure is rare until the end of the pregnancy, when many cases clear up spontaneously. The ultimate fate of the remainder is of interest. One series of statistics is reported by Naujocks and another by Gladys Dodds. The latter had the opportunity of following a group of cases for two years and found that chronic pyelitis or chronic bacteriuria developed in about half. The clinic with which I am connected and other clinics have pediatric departments which observe many cases of pyelitis in childhood. Many of these patients will in later years be followed through pregnancy in the same clinic and I believe that in the next five or ten years some interesting figures should be obtained bearing on this point. The posterior urethra is a cause of continuation of symptoms is worth emphasizing. It is true of any case of pyelitis. It not infrequently happens that after a bacteriologic cure symptoms persist until the urethra receives treatment. I find the indwelling catheter useful in certain instances of postpartum urinary disturbance.

Dr. J. I. HOFBAUER, Baltimore. At Johns Hopkins I have not observed dilatation of the ureters in pregnant monkeys. My work (*J. Urol.* 20:413 [Oct.] 1928) stresses the presence of bile salts and cholesterol in the blood as probably accounting for the dilatation of the ureter during pregnancy. It is only in the human being that definite impairment of liver function is demonstrable during pregnancy, with bile salts present in the blood. Dr. Crabtree rightly emphasized long standing infection as the factor responsible for the persistence of dilatation of the ureter following pregnancy and for stricture formation. I fully share his views. In every case the presence or absence of ureteral narrowing should be ascertained and, in addition solution of pituitary in small doses should be given over a protracted period of time in order to restore ureteral activity. In Marburg, Germany, every case of pyelitis of pregnancy is

now being treated with solution of pituitary and splendid results are being reported. In a recent publication, intractable cases are reported which well responded to solution of pituitary. (Jonn, J. L. *Surg. Gynec. & Obst.* 53:640 [Nov.] 1931). In a previous paper, histologic evidence was adduced which showed that bladder damage may occur during obstructed labor with injury to the muscle fibers and diffusion of blood. During the puerperium the bladder may be induced to contract by solution of pituitary. Failing this, I insert the catheter.

Dr. J. S. LEWIS, Youngstown, Ohio. I first year at the New Orleans meeting Dr. Baker and I presented an exhibit in which we showed the distention of the upper urinary tract in pregnancy. Since then we have added almost 100 cases. At that time we felt this was a mechanical problem and still feel that most of it is mechanical. We have not overlooked the hormonal element that Dr. Hofbauer brought out but we think we have a few facts to back up the idea that it is chiefly mechanical. A ureteral catheter will not drain the pelvis completely. One cannot distend any normal cavity for a long time without having it lose its normal tone. Give these patients an intravenous dye after delivery and one gets an almost normal pyelogram, make a retrograde ureterogram and one cannot believe it is the same pelvis. They have a residual atony that persists for a long time. In regard to Dr. Hofbauer's remarks, I believe that monkeys bring by their tails even when pregnant. If this process is mechanical there are two things that it should be possible to show. 1. It should be present in tumors, cysts and some cases of tubal abscess, as I have shown. 2. It should be absent in the quadruped, so far I have been unable to show it in experimental animals.

Dr. F. H. LAMM, Chicago. Since the question of the use of solution of pituitary as a remedial agent in this condition has been brought up by Dr. Hofbauer, I wish to call attention to the fact that twenty-four hours before a woman goes into labor a marked diuresis occurs. This is the physiologic action of solution of pituitary in the blood. Also, it has been shown that the diuretic action of solution of pituitary cannot be demonstrated in pregnant dogs in the laboratory. Therefore there is something in the blood during pregnancy that inhibits the normal action of solution of pituitary during pregnancy. Its purpose is to prevent the uterus from aborting. Just before and during labor this inhibiting action is overcome possibly by physiologically produced solution of pituitary. I have repeatedly seen such cases. In one case the patient entered my clinic at the University of Iowa, diagnosed typhoid because of the toxic symptoms and the height and character of the temperature curve. She developed placenta previa and was delivered at seven months. She was advised to prevent conception for two years because of the severity of the pyelitis. She became pregnant in two months. She reported for observation every month for a period of three or four days. There was no recurrence of the pyelitis during the pregnancy, labor or postpartum. This brings up the important question of why all these women do not develop puerperal sepsis. It is very rare to have puerperal sepsis, and it is very hard to understand how a woman can be delivered from below without developing a puerperal sepsis. Acting on the theory that they must have a protective immunity, I found that these women had a high titer of agglutinins for the organisms found in the urine. I also found that a positive agglutination can be obtained and that one can take the organism of one woman and the serum of another woman with pyelitis. I wish also to remark on the anemia of pregnancy as predisposing to pyelitis. I think it might better be assumed that the anemia is caused by the pyelitis. This is important obstetrically for in anemia if the patient loses much blood post partum she may die. I have seen death occur after the loss of only 800 cc of blood and the postmortem reveal no other cause than anemia. As to the question of the cervix being an etiologic factor some work by Maryon in my clinic shows that the organism that causes cervicitis is not *Bacillus coli*, which is the most common organism in pyelitis, but the enterococcus. I do not feel that the use of the indwelling catheter during the acute stage of pyelitis is justified either in the bladder or in the ureter.

Dr. ABRAHAM RAVICH, Brooklyn. Why bring in a complicated mechanism such as the hormones involved in pregnancy to explain dilatation of the ureters and renal pelvis with

its frequent association of pyelitis of pregnancy when it can all be explained by mechanical pressure exerted by an enlargement and displacement of the uterus and adnexa during pregnancy? The same pathologic process in the ureter often occurs with fibroid uteri, yet no one would consider this an effect of hormones. Can one attribute gallbladder stasis so common in late months of pregnancy to hormones also? It seems to me that the entire problem is a mechanical one. For the same reason the varicosities seen on the vulva and legs during pregnancy may also be attributed to mechanical stasis. Owing to the pressure of the pregnant uterus on the pelvic portion of the ureter, it is very difficult to get a clear conception of the amount of dilatation present in this portion of the ureter either by retrograde or by excretory ureterograms. Several years ago a patient in her eighth month of pregnancy came to me with a very large calculus 1 by one half inch impacted in the left ureter at the pelvic brim. The dilatation of the ureter down to the ureterovesical junction, however, was so great that, within four days after the mere passage of a 6 F catheter beyond the calculus the stone was spontaneously expelled, with relief of the pyelitis on that side.

DR E. G. CRABTREE Boston Drs Lee and Mengert have given an excellent pyelographic demonstration that stony of the pelvis and ureter is not cured by delivery but persists for a considerable time. These kidneys are distensible without pain to an extent considerably above normal, but they will eventually return to normal. There are two kinds of patients as indicated by the readiness with which postpartum pyelitis follows bladder retention. In those instances in which infection already exists, febrile reaction occurs immediately with the onset of retention; in the other type of case, in which the urine is uninfected catheterization may be carried on for some days before a febrile reaction occurs because the infection must be introduced and cultivated before it reaches sufficient magnitude to produce fever. If then one knows that an infection already exists I feel sure that the wisest procedure, on the recognition of retention is to institute constant drainage immediately. The patient herself should not be forgotten. Good hygiene, including water drinking and care of the anemias of pregnancy and a patient to develop tolerance for infection that her pregnancy may be both comfortable and safe even though those infections are seldom cleared in pregnancy. The anemias of pregnancy demand special attention and should be combated. Certainly the patient should be protected by hygienic measures after delivery that she may rid herself as quickly as possible through nature's own protective measures. A transfusion is good therapy in certain cases of pyelitis of pregnancy. Much can be done with proper diet, both to prevent the development of anemia and to restore the patient's general condition after it has occurred.

DR G. C. PRATHER Boston The lack of temperature reaction following delivery has been mentioned also the lack of febrile reactions. It has been my impression for some time that the patients with pyelitis whom I saw in its febrile form during pregnancy seldom got into difficulties with fever following delivery. I went over my figures for the past three years and found that in eighty cases of pyelitis in pregnancy sixty presented no rise in temperature following delivery. In twenty cases or 25 per cent, in which there was some hyperpyrexia post partum, by no means was the urinary tract infection the only factor responsible for this temperature. My impression, therefore has been correct that about 75 per cent of the patients with pyelitis during pregnancy will show no febrile complications following delivery, while the remainder may have a normal temperature during pregnancy but have a kick up following delivery.

DR W. J. WALLACE Oklahoma City Postural treatment is essential and I use it as a routine procedure. After parturition the foot of the bed is raised for a distance of from 4 to 6 inches and kept at that height as long as the patient is in the hospital. Twice daily after the third day the foot of the bed is raised an additional distance of 2 feet or an angle of about 35 degrees, for at least an hour at a time the height and length of time depending on the individual patient. During half of this hour I have the patient lie on her stomach without a pillow. The Trendelenburg position helps these conditions. In these

cases I find a complicating condition of posited kidney as well as the associated enteroptosis and a general sagging of all the associated organs. In all cases of pyelonephritis, a selected diet rest, alternating antiseptics and the positions as outlined will add materially to recovery.

DR ROBERT GUTTERRIZ New York In spite of all the valuable pyelographic and pyeloscopic data now available, it is obvious that the dynamic contraction of the upper urinary tract in its emptying time is inhibited in cases of pyelitis of pregnancy. The stasis produced in the upper urinary tract is responsible for its physiopathologic condition which causes hydro-ureters and hydronephrosis as well as pyelitis and pyelonephritis. I am still inclined to believe that there are instances in which cases of pyelitis of pregnancy may be treated conservatively with the method of the indwelling ureteral catheter. I have recently examined a young pregnant woman who had a hydronephrosis which the family surgeon mistook for acute appendicitis and on which he was ready to operate. Because the patient had pus in the urine and other urinary symptoms I was asked to examine her. I found that she had an infected hydronephrosis of large size. After inserting an indwelling catheter which I left in place for over five days, I was able to suction out about 50 cc of purulent urine from the right kidney pelvis. The temperature then dropped to normal the urine cleared up and, in agreement with the last speaker, I think that the knee-chest position for a half hour, three or four times a day, was also of great assistance in this case. The pressure of the uterus on the ureters was thus relieved and a better drainage secured. The patient's condition cleared up entirely and she had no further difficulty with her labor. I feel that the indwelling ureteral catheter has a definite use in the treatment of cases such as this, where a No 6 or No 8 ureteral catheter should be employed, having been previously boiled so as to be soft and not produce any trauma.

ROENTGEN EVIDENCE OF HEALING IN DUODENAL ULCER

DANIEL M. CLARK, MD

AND

MILTON J. GEYMAN, MD

SANTA BARBARA, CALIF.

The most conspicuous defect in the present accepted methods for the management of peptic ulcer is the lack of any dependable means of establishing that the lesion is healed. The interval between the onset of symptomatic relief, which is usually effected within a few days after the institution of medical treatment, and the complete healing of the ulcer undoubtedly varies greatly, and the time at which the latter takes place in individual cases cannot be established by any known procedure. Besides enabling one to answer the patient's persistent question "Is my ulcer healed," such a procedure, if it could be brought to light, would result in other advantages. By its employment in a sufficiently large number of controlled cases, information might be gathered as to the relative effectiveness of the widely varying methods of treatment now in vogue, thus ending many an argument. The patient would be benefited more directly in an economic way. So-called recurrent ulcers are in many instances simply the result of permitting the patient to relax dietary restrictions and discontinue alkalinization before the healing process has been completed. Such patients might be saved the discouragement and added expense of a recurrence of symptoms. On the other hand, postmortem observations and the experience of many internists would indicate that there is a large group of cases in which peptic ulcers heal

with little or no treatment. In the latter event the patient would be spared the expense and tedium of an unnecessarily prolonged period of treatment. Any method by which information may be gained regarding healing of such lesions no matter how meager that information may be, seems to us a matter worthy of investigation and evaluation.

The idea of employing the roentgen ray to detect healing in peptic ulcer is not new. Until recently however, its use has been confined almost entirely to penetrating gastric ulcers. Friedenwald and Baetjer¹ were among the first to appreciate its usefulness in this direction, and the roentgen demonstration of niche disappearance in gastric lesions following treatment is now a commonplace observation. As a result a certain amount of information has been added to our knowledge of the prognosis in gastric ulcer but the greatest value of the procedure lies in establishing the benignancy or malignancy of ulcerating lesions of the lesser curvature the former almost invariably showing a sharp reduction in size, if not complete disappearance after a few weeks of medical treatment.

The roentgen demonstration of healing in duodenal ulcer has been quite another matter. Since the niche sign is the only pathognomonic roentgen evidence of an

success in only 13 per cent of cases. Kirklin⁴ later found niche evidence in 15.24 per cent of 1,791 cases of duodenal ulcer seen at the Mayo Clinic in 1930. Fluoroscopic observation is inadequate, moreover, in that one can scarcely remember the exact size and location of a niche seen momentarily several weeks previously.

COMPRESSION TECHNIC

As a result of the work of Berg,⁵ Akerlund,⁶ Albrecht⁷ and others a refinement in gastro intestinal technic has been developed which permits accurate visualization and film recording of a much higher percentage of duodenal ulcer niches than was heretofore possible. This procedure is known to roentgenologists as compression technic and consists simply of fluoroscopy and the making of roentgenographic studies while the part in question is compressed by some device. In this manner the walls of the duodenal bulb are approximated and all but a thin film of barium is squeezed out. The barium retained in the crater of the ulcer is thus brought into sharp relief. The procedure is not difficult, can be accomplished in a short time at small expense, and requires only slight additional equipment, but the correct interpretation of results demands considerable experience in its use.

Employing this method, Akerlund was able to obtain niche evidence in 60 per cent of 109 cases of duodenal ulcer. Berg was similarly successful in over 50 per cent of cases. Our own experience agrees quite closely with these figures.⁸ During the year 1932 we found positive niche evidence in 54 per cent of all cases of duodenal ulcer.

We have recently studied twenty five such cases on one or more occasions after the institution of treatment. In all instances, positive niche evidence has been obtained and recorded on film studies at the initial examination. Although the series is inadequate in several respects, we feel justified in drawing certain conclusions.

SIGNIFICANCE OF NICHE DISAPPEARANCE

The value of the roentgen ray in detecting healing in peptic ulcer depends in a large measure on what one may conclude from niche disappearance per se. Can one say that an ulcer is completely healed simply because the niche is no longer visible on roentgen examination? If niche disappearance does not mean that complete healing has taken place, then at what stage in the process of healing does it occur?

In three cases reported by Buckstein the patients were free from symptoms at the time niche disappearance

Fig. 1 (case 1) — Duodenal bulb under compression showing niche (N) with corona of edematous mucosa (C).

Fig. 2 (case 1) — Appearance after fifteen days of medical treatment. The niche has disappeared but the patient still has interstials of ulcer distress in spite of strict adherence to diet.

active peptic ulcer, healing can be observed only in those instances in which the niche is seen and permanently recorded prior to the institution of treatment. The fact that this can be readily accomplished in a high percentage of gastric ulcers accounts for the success commonly attained in showing changes in size or disappearance of such lesions following treatment.

The trouble encountered in applying the same procedure to duodenal lesions lies in the difficulty in demonstrating the niche. Certainly not over 10 per cent of duodenal ulcer niches are visible on film studies of the barium filled bulb in the general run of cases. As a matter of fact, the incidence is probably considerably lower than that. Buckstein² was able to demonstrate niche disappearance in three such cases, however.

It is true that the niche may be observed fluoroscopically in a somewhat larger group, but even as expert fluoroscopists as Carman and Sutherland³ reported

nice was demonstrated and he felt that in such instances it might be safely said that the ulcer was completely cured. Although it is not specifically mentioned, one assumes that the patients were no longer under treatment at the time the second examinations were made. That niche disappearance *per se* does not imply complete healing, however, has been repeatedly impressed on us by the fact that symptoms may persist or recur after all traces of the niche have disappeared even though the patient is still under strict medical management. The following cases illustrate the point.

CASE 1—M. G., a white man aged 35, had epigastric distress of a burning character for one week. On examination, an *en face* niche was demonstrated on the posterior wall of the bulb. A shallow incisura was noted at the same level on the greater curvature of the cap (fig 1). Fifteen days later the niche was no longer demonstrable, although the incisura was still present (fig 2). In spite of rigid adherence to diet the patient had typical ulcer distress at times for several months.

CASE 2—Mrs. D. L. aged 27 had typical ulcer distress for three weeks. On examination June 13, 1932, the duodenal bulb showed an elliptic deformity along the greater curvature. Compression studies revealed a pea-sized niche on the greater curvature toward the anterior wall (fig 3). The symptoms were relieved within twenty-four hours after the institution of

the human being does not lend itself well to experimental study, observations as to the method by which ulcers heal have been obtained through three sources: (1) peptic ulcer produced experimentally in animals, (2) patients who have been subjected to surgery after a preliminary period of preparation during which the patient was on an ulcer diet, and (3) patients who have died from some other cause during the course of ulcer treatment.

Mann and Williamson⁹ were the first to report success in the experimental production of peptic ulcer in dogs, after a secondary anastomosis which segregated the ulcer in such a way that no gastric contents passed over it. Mann¹⁰ made a thorough study of the manner in which healing takes place. "Macroscopically the first evidence of healing is a cleaning of the base of exudate and debris, and the formation of a smooth surface. Then the ulcer appears to grow shallow due to a filling in of the base by new granulation tissue. The overhanging mucosa and this granulation tissue completely fill the base of the ulcer. Gradually the edges of mucosa grow around the periphery toward the center, usually pushing the granulation tissue up and out like a plug. At first the mucosa is thin and smooth. Gradually it thickens and becomes thrown into folds."

Fig 3 (case 2) —Compression study of duodenal bulb showing large ulcer niche (N) surrounded by corona of thickened mucosa (C).

Fig 4 (case 2) —Similar study after three weeks of treatment. The niche is much smaller but still retains a small fleck of barium; the surrounding inflammation and edema have subsided.

Fig 5 (case 2) —Appearance after a recurrence of symptoms six months later. The cap is deformed but no niche can be detected.

treatment. Reexamination, July 7 (fig 4), showed the niche greatly reduced in size but still quite definitely present. There had been no symptoms during the interval. August 22, no trace of the niche could be detected. The patient remained under treatment until the Christmas holidays, during which time indiscretions in eating and drinking caused a return of typical ulcer distress. Examination, Jan 9, 1933 (fig 5), failed to show any evidence of a niche, although the bulbar deformity was somewhat increased.

On the other hand, it is quite possible for a patient to be free from symptoms although the niche remains demonstrable. According to Akerlund, "it is not unusual that a niche may persist, even if diminished in size, after the pains have completely disappeared and that patients with obvious niches are on the whole free from pains." This evidence seems to us conclusive proof that there is no fixed relation between niche disappearance and symptomatic relief and that niche disappearance does not imply complete healing.

How then, can one explain the failure of an incompletely healed ulcer to retain barium? We feel that a satisfactory explanation is offered by the experimental and pathologic evidence. Although duodenal ulcer in

Caylor¹¹ described a similar process of healing and found a granulation bud present in twenty-five of thirty gastric ulcers in man which were healing at the time they were resected. Crohn, Weiskopf and Aschner¹² and others also observed this sequence in human beings. Bliss¹³ was unable to demonstrate the granulation bud in several patients who died following surgery or during the course of medical treatment or on whom duodenal ulcer was an incidental finding at autopsy. He nevertheless felt that the filling in of the defect by a granulation bud represented one phase, probably an early one, in the healing process.

To appreciate the true value of the roentgen ray in detecting healing in peptic ulcer, therefore, one must realize that although niche disappearance unquestion-

ably indicates a favorable initial response to treatment, it does not necessarily mean that the lesion is healed. When the surrounding edema and infiltration subside and the crater becomes plugged with a bud of granulation tissue, the niche no longer retains barium and is not demonstrable roentgenologically. This probably occurs relatively early in the process of healing.

TIME OF DISAPPEARANCE OF NICHE

Mann made the following observations on his experimental ulcers. Within four days its base was clean and a thin protecting covering had formed over it. In ten days the ulcer usually had greatly decreased in diameter and depth. On the twentieth day three fourths or more of the base would be covered with mucosa. Before the thirtieth day it was almost impossible to find the site of the ulcer. It must be remembered, of course, that this occurred under artificial conditions unattainable in the human being. In one case reported by Bliss the patient died sixty-five days after an operation for perforation of a duodenal ulcer. The lesion was still in an early stage of healing. Another died fifty-three days after gastro-enterostomy. The healing process was well advanced but the crater was still present macroscopically.

Fig. 6—Barium filled duodenal bulb showing a normal contour

Fig. 7—Compression study of the same bulb. A definite ulcer niche (N) is now clearly seen on the posterior wall

It has been impossible for us to strike an average time of disappearance, since many of the patients studied lived at distant points and returned for a check-up examination only after an interval of several months. Such an average would be of doubtful practical value, as there is undoubtedly the widest variation in the amount of time required for the niche to disappear. In one of our cases all roentgen evidence of the niche was gone after nine days of treatment; in another after fourteen days and in several after three weeks. In a few instances a much longer time was required. In one case the niche was larger after four months of careful management than at the original examination. The degree of chronicity of the ulcer, its size and depth and the age of the patient are among the factors responsible for the wide variation in time required for healing to take place.

Two cases in the series presented both gastric and duodenal niches and in both instances the gastric lesion was the first to disappear. Emery and Monroe¹⁴ studied five cases of coincidental gastric and duodenal ulcer. In all but one the duodenal ulcer appeared worse or no better, whereas in all but one the gastric ulcer

disappeared. It seems probable, therefore, that in general gastric ulcer niches disappear more quickly under treatment (heal more rapidly) than duodenal ulcers.

RELATION OF NICHE TO CONTOUR DEFORMITY

Owing to the difficulty heretofore encountered in demonstrating the niche in duodenal ulcer, roentgenologists have learned to recognize ulcers in this region by contour deformities of the barium-filled bulb. Much has been written on the subject and a high degree of diagnostic accuracy has been attained. This method of diagnosis has been based on the assumption that an ulcer in the duodenum predicates a characteristic deformity of the barium-filled bulb in the form of cicatrix and/or spasm. These deformities have been classified and attempts made to draw conclusions as to healing from changes in the contour deformity following treatment. Thus, Hamburger¹⁵ reported three cases in which he felt that he could detect a lessening of the deformity after treatment. His illustrations were not convincing. Emery and Monroe classified the different types of bulbar deformities and made comparisons before and after treatment. They concluded that no reliable information regarding healing could be obtained by this method.

The possibility of obtaining any information regarding healing from such studies seems to us extremely small. In the first place it is not at all rare to find an ulcer in a bulb which presents no characteristic contour deformity when filled with barium. If treated early and effectively such a lesion may heal without any deformity whatever. Such a case is illustrated in figures 6 and 7.

In a much larger group, characteristic bulbar deformity not only is present during the active stage of the lesion but persists practically unchanged for an indefinite period thereafter. This has been frequently commented on, so often in fact that it has given rise to the well known but erroneous roentgenologic dictum: "Once an ulcer, always an ulcer." The futility of drawing conclusions as to healing from this type of case is well expressed by Emery and Monroe: "It is obviously absurd to make a diagnosis of an active duodenal ulcer by the finding of a deformity, give some form of treatment and on finding the same deformity at a later examination explain its persistence on the basis of scar tissue and assert that the disease is cured." The persistence of deformity after healing of the lesion is well illustrated in figures 8, 9 and 10. Characteristic bulbar deformity per se, therefore, means that an ulcer is or has been present but does not permit one to conclude that the lesion is or is not active. The absence of bulbar deformity does not preclude the possibility of an active ulcer. Even in those instances in which a slight bulbar deformity noted at the original examination disappears after treatment, one can never be sure that the original deformity was not due to spasm rather than to ulcer.

EFFICIENCY OF VARIOUS FORMS OF TREATMENT

All but one of the patients studied were treated with conventional dietary measures. The exception was a woman who had failed to respond to a strict dietary

regimen Following our first examination, at which both gastric and duodenal ulcer niches were demonstrated, she was put on mucin treatment. Ten days later, all traces of the gastric niche had disappeared and the duodenal ulcer was definitely smaller. At the end of three weeks neither lesion could be visualized. This single case proves nothing in regard to the comparative value of the two forms of treatment but it does suggest the feasibility of using the speed of niche disappearance as an index in developing some real evidence as to the effectiveness of the different methods of ulcer management in use at present.

CONCLUSIONS

1 In more than half of all cases of duodenal ulcer the roentgen ray has a definite value in determining the response of the lesion to treatment.

2 Roentgen disappearance of a duodenal ulcer niche following treatment indicates a favorable initial response but does not mean that the ulcer is completely healed.

3 There is a wide variation in the amount of time required for disappearance of the niche. As a general rule, duodenal ulcers heal more slowly than gastric ulcers.

tion again to the fact that one can demonstrate these deformities by placing the patient in a proper position under the fluoroscope. Taking the films without moving the patient from that position will demonstrate the deformity and the niche much more often than if one just lays the patient down on the table and makes the exposures. I mean to say that I do not believe one can put the patient in the prone position to demonstrate pathologic conditions by the hit or miss method. It must be done under the fluoroscope. When the patient is in that position the films should be made without allowing the patient to move at all. Having done all these things I am still uncertain that the demonstration of a niche at one examination and the inability to demonstrate it at another examination is proof that the ulcer is healed.

DR B. R. KIRKLIN, Rochester, Minn. I understood the authors to say that one cannot depend on constant deformity alone for the diagnosis of duodenal ulcer. I assume they mean that constant deformity of the duodenal bulb without a demonstrable crater is not sufficient evidence for this diagnosis. If this is what they mean I am disappointed to hear the statement and must take exception to it. It is my opinion that many roentgenologists who have had wide experience in making diagnoses of duodenal ulcer and have had the opportunity of checking their diagnoses at the operating table or at necropsy will not agree to the statement. My associates and I have been making diagnoses of duodenal ulcer for many years in cases which presented constant deformity of the bulb, with or with-

Fig 8—Similar study of same case after six months of treatment. The niche has disappeared; there is no residual deformity of the bulb; the patient is symptom free.

Fig 9—Compression study of duodenal bulb showing gross contour deformity and two well defined ulcer niches (N N).

Fig 10—Same case after three months of treatment. The niches have disappeared and the patient is free from symptoms, but the contour deformity remains essentially unchanged.

4 Contour deformities of the barium-filled bulb are not entirely dependable in the diagnosis of duodenal ulcer, and they are of little or no value in determining the response of a lesion to treatment.

ABSTRACT OF DISCUSSION

DR GEORGE W. GRIER, Pittsburgh. If the authors feel that the disappearance of the niche on x-ray films is not proof that the ulcer is healing, I agree with them. There are so many unknown factors regarding ulcer of the stomach and duodenum that such conclusions as these cannot be drawn until those uncertainties are cleared up. It is not known for certain whether cases of ulcer that keep recurring are entirely healed or whether they heal and break down again. I am not certain that the disappearance of a niche which might be caused by the growth of granulation tissue in the crater would mean an entire healing of the ulcer, because if epithelialization does not take place the ulcer is not yet healed. Unsatisfactory epithelialization may account for some of the cases that show symptoms after the niche has disappeared on the x-ray film. It is my impression that one sees the niche in duodenal ulcer very often if one gets the patient in a proper position and sees the niche in profile. I have not been able to demonstrate a niche in a duodenal ulcer as well with the compressor as by the older method of rotation of the patient. I should like to call atten-

tion to a crater, and in checking our results we have been gratified to learn that the errors amounted to less than 4 per cent. May I ask the authors on what experience they base this assertion? Reference has been made to the low percentage of craters reported by myself as compared with those reported by Akerlund and others. I am sure that if one selects a group of cases presenting clinical evidence of active duodenal ulcer, a high percentage of craters will be found, but if one examines as a routine all patients presenting the slightest gastro-intestinal symptoms, either past or present, many will show only a deformity representing an inactive ulcer or ulcer scar, and a smaller percentage of the group will show craters. The latter is the procedure at the Mayo Clinic, and, I am sure, accounts for the fact that fewer craters have been visualized. I think that radiologists are justified in interpreting deformity without a crater as duodenal ulcer, leaving it to the clinician to determine whether the patient is suffering from an active ulcer at the time of the examination, for I am certain that many patients with active ulcer show no crater at the time of examination. I think it would be misleading to teach that it is necessary to see a crater before a diagnosis of duodenal ulcer can be made. In order to elicit evidence of a crater it is necessary to study the mucosal relief, either by manipulation or by pressure apparatus, which has recently been emphasized on the continent. However, the latter method is not new, for roentgenologists have been studying the mucosal relief of the stomach and duodenum since Holzknecht's time. The only new

development has been the apparatus recently devised for making a record of a mucosal pattern on the film.

DR DANIEL M. CLARK, Santa Barbara, Calif. Dr. Grieco's understanding of our conclusions as to the significance of niche disappearance is entirely correct. We have tried to emphasize that disappearance does not imply complete healing. We briefly described the compression technique in this paper to explain the method by which the present studies were made and not to champion its efficiency as compared with conventional methods of gastro-intestinal study. Dr. Grieco's dissatisfaction with the method is not unusual. In our own experience its advantages were appreciated only after a prolonged period of persistence and patience. Dr. Kirklin has misunderstood our statement with regard to roentgen evidence of ulcer. We said that constant bulbous deformity means that ulcer is or has been present but that the deformity itself does not constitute sufficient evidence to establish the presence of an active ulcer. In other words, deformity may persist after the ulcer has completely healed. Niche evidence means active ulcer but its absence does not rule out ulcer. We can demonstrate the niche in only slightly more than half the cases in which we make a diagnosis of duodenal ulcer. We cited the Mayo Clinic statistics on niche visualization because it was the only available series on the subject in which compression technique had not been used. Their relatively low niche incidence does not in any way reflect against their accuracy in diagnosing duodenal ulcer.

PERFORATED PEPTIC ULCER WITH INTERMITTENT LEAKAGE

HARRY A. SINGER, M.D.
CHICAGO

It is universally believed that, following the initial violent pain the clinical picture and course of a perforated peptic ulcer are relatively uniform. The current teaching with regard to the symptomatology of ruptured ulcer subsequent to perforation may be summarized as follows. In the average case the intense pain of onset continues unabated unless relieved by large doses of morphine or by surgical intervention. If operation is not performed the clinical picture of a diffuse suppurative peritonitis supervenes preceded at times by a temporary subsidence of pain the so-called period of quiescence or repose. In all but a small proportion of cases, generally stated to be less than 5 per cent, the infection progresses rapidly and leads to death within a few days. The small group of patients who recover from the diffuse, purulent peritonitis pass through a stormy convalescence during which surgical drainage of one or more intra-abdominal abscesses is often required.

The classic picture and course following acute perforation as here presented, are by no means constant. In a large percentage of cases the intense initial manifestations rapidly subside and spontaneous recovery ensues.¹ Indeed, in a considerable number of instances within a few hours after the annihilating pain of rupture is experienced the patient feels relatively well and is free from pain except perhaps on sudden movement. If such a patient is first seen several hours or more after the perforation has occurred the clinical picture he presents will be far different from the one described in the classic case. Instead of eliciting the signs of a diffuse, progressive peritonitis in a toxic patient, one finds evidence of a localized, mild, receding inflamma-

tion in an individual who is comfortable and apparently well. As a matter of fact if the patient is not seen before twenty-four or more hours have elapsed, except perhaps for a localized residual soreness, the patient is found to be practically normal. On account of the tranquillity of the clinical manifestations in the post-perforative period Singer and Vaughan have designated this variety of perforation as *forme fruste* to distinguish it from the classic type. The *forme fruste* is closely akin to the "subacute" perforation of Lund² and of Moynihan³ and the covered (*gedeckte*) perforation of Schmitzler.⁴

The reason for the mild postperforative course in the *forme fruste* type is that, immediately or shortly following rupture and extravasation the hole becomes spontaneously sealed, plugged or covered. Because of this occurrence only a limited quantity of gastroduodenal content often trifling in amount, reaches the peritoneal cavity. The degree of soiling is so slight that the peritoneum readily neutralizes the irritating fluid and destroys the relatively few micro-organisms that escape from the stomach or duodenum. The permanent closure of the hole is accomplished by firm adherence to a neighboring organ, especially the liver, but also the pancreas and gallbladder by attachment to the anterior abdominal wall or a tag of omentum and by organization of a fibrinous exudate or of fibrin over a food plug.

In addition to the classic and *forme fruste* perforations there occurs a third type which although relatively uncommon is of both importance and interest to the clinician. In this third form the patient generally gives a history of a typical *forme fruste* rupture with the usual mild postperforative course. Instead however, of recovering completely and more or less permanently he develops in close succession a second similar attack which likewise may be followed by symptoms and signs of a benign localized peritonitis often with prompt recession. The improvement is not as in the so-called period of repose merely subjective and only apparent but is also objective and actual. A third and even a fourth attack may supervene. In most instances the second or third outbreak is followed by persistence of symptoms and the development of a clinical picture quite comparable to that referred to as classic. The unusual sequence of events is best explained by assuming intermittent leakage from a hole in the stomach or duodenum.

The mechanism involved in intermittent leakage is presumed to operate as follows. The initial rupture is apparently followed by extravasation of gastroduodenal content which is limited in amount by apposition of a neighboring structure or fibrin or by obturation with a plug of food mucus or coagulated exudate. The clinical manifestations are those of a *forme fruste* rupture. Separation of the loose adhesions or dislodgment of the plug after a period of time permits a recurrence of the leakage and its attendant manifestations. Should sealing of the hole follow before much material escaped into the peritoneal cavity, the symptoms and signs of a *forme fruste* perforation are

repeated. This performance may thus recur several times. At any time, however, spontaneous closure may fail to occur and the escape continue without restriction. In this event the severe pain will fail to abate but will persist and become associated with the usual signs and symptoms of a classic perforation. Repetition of the leakage is prone to occur when following the initial extravasation. Ordinary precautions in the prevention of further escape, viz., abstinence from ingesta and restriction of activity are not observed. A basis for the foregoing explanation of successive attacks of intense, more or less diffuse abdominal pain associated with peptic ulcer is found in a series of clinical observations, some of which will be recorded later.

In reading clinical reports on perforated ulcers, one occasionally encounters a case in which the description of the symptoms is very suggestive of intermittent leakage. An interpretation is generally omitted and when given is not at all in accord with the conception stated. A case in point is related by Walton⁶ in connection with his discussion of acute onset of perforated peptic ulcer. He writes:

A S., a married woman aged 42 had for many years suffered with the characteristic attacks due to a chronic gastric ulcer. Four days before admission she was suddenly seized with violent pain all over the abdomen, which later became localized to the epigastrium and was accompanied by vomiting, which only gave partial relief to the pain. The pain was more severe than any she had experienced in her previous attacks and was sufficient to confine her to bed. After two days it had improved and she was able to return to her work. At 5 P.M. on the evening before admission she was seized with another attack of severe pain which had not left her but had steadily increased and was now described as being agonizing in character. It commenced in the epigastrium and passed to the lower abdomen, "seeming to screw her up." She presented typical physical signs and at operation was found to have a large perforation near the pylorus.

This case is offered by Walton to illustrate the character of what he terms premonitory symptoms which precede perforation. The severe pain experienced by the patient in the foregoing case report four days before admission is apparently considered a premonition of the impending rupture. Walton presumably correlates the second attack of violent pain suffered the evening prior to entrance with the time of occurrence of actual perforation of the ulcer.

Pain which differs decidedly from that of ordinary ulcer distress and also from that of true rupture not infrequently precedes actual perforation. For a period of several minutes, hours or even days prior to rupture the patient experiences an intensification of his former ulcer distress, which, however, does not reach a degree sufficient to require morphine or to force the patient to take to bed. Vomiting frequently accompanies the pain. At times, in addition to the exaggerated simple ulcer discomfort, a sharp, stabbing pain is felt at intervals, generally provoked by sudden or forceful muscular contraction as coughing, sneezing, deep breathing or twisting. It would appear reasonable to ascribe the aggravated simple ulcer distress to penetration and the intermittent stabbing pain to a fibrinous deposit on the serosa as evidence of extension of the inflammation chemical, bacterial or both, to the peritoneal coat. These two types of pain heralding as they do an impending perforation are to be looked on as premonitory symptoms. However intense pain such as was

apparently experienced by Walton's patient four days prior to admission and such as is described in the reports to follow is quite characteristic of actual perforation with extravasation. Violent pain of sufficient severity to annihilate a previously healthy individual can hardly be considered prodromal.

REPORT OF CASES

CASE 1—E. M., a white man, aged 36, who was addicted to the use of alcohol, entered the Cook County Hospital, Aug. 3, 1931, at 11 A.M. He was rather uncooperative and on this account the history and physical examination were not entirely satisfactory. The essential statements recorded in the patient's chart are as follows: Four days prior to entrance, he began drinking heavily. On the second day of his debauch he noted epigastric pain, which, he stated, was mild at the onset but increased gradually in severity until it became quite intense. Physically, tenderness and rigidity were found in the epigastrium and over the upper half of the right rectus. The abdomen however was scaphoid, and peristaltic sounds were present, though diminished in quantity. The patient's breath

Fig. 1 (case 2)—Pneumoperitoneum in a patient with intermittent leakage from a perforated peptic ulcer. Fluoroscopically the air (indicated by arrow) could not be made to shift with change of position of the patient, demonstrating that the gas was encapsulated. As this roentgen observation was made very shortly after the fourth attack of pain too soon for encapsulation to have occurred as a result of leakage at that time it is logical to assume that the escape of air took place previously.

had a strong alcoholic odor. The diagnosis made by the admitting physician was alcoholic gastritis. This opinion was concurred in by two of the attending physicians after the patient had reached his ward. Here the stomach was aspirated and 1400 cc of a thin watery material obtained. It had an odor of alcohol and kerosene and on titration was found to have 25 degrees of free and 60 degrees of total acidity.

The patient was first seen by me at 6 P.M., seven hours after admission. At this time he was far more comfortable and quite cooperative. By exercising pains in questioning and devoting a requisite amount of time I obtained the following pertinent history. The patient had suffered from ulcer distress periodically for several years. His present attack, which began July 31, three days prior to admission was characterized by pain of a more severe character and was more continuous than his former ulcer distress. Although his sleep was disturbed by it the pain was at no time of such intensity as to require him to take to bed or to summon medical aid. However at 11 A.M. on the day of entrance August 3 the pain suddenly changed its character and became extremely violent. It began

⁶ Walton, A. J. *The Surgical Dyspepsias*, ed. 2, London: Edward Arnold & Co., 1930, pp. 102-103.

in the epigastrium but rapidly spread throughout the abdomen. He writhed about in agony and groaned loudly. Since the pain was so excruciating and since it showed no tendency to moderate he requested that he be moved to a hospital immediately.

The police ambulance was summoned and within ninety minutes of onset of the intense pain the patient was in the hospital admittance room. During the trip he suffered sharp, stabbing

Fig. 2 (case 3)—Minute amount of free air under the dome of the right diaphragm two days after the onset of perforation of a peptic ulcer with intermittent leakage. Clinically it was apparent that the aperture was securely closed.

pain with each jar of the automobile and although anxious to reach the hospital as soon as possible he repeatedly implored the chauffeur to drive slowly and cautiously. After the patient arrived in the hospital the pain began to moderate. As a matter of fact he noted that as long as he lay absolutely quiet on the hospital cart he was comparatively comfortable. Because of the pain occasioned by movement the patient talked as little as possible and resisted every attempt to move him during the examination. At the present time he was rather comfortable, although sudden motion still elicited pain.

In the light of this additional information the diagnosis of perforated ulcer seemed likely. At this time the tenderness had diminished in degree and extent and was practically limited to the epigastrium. A shifting zone of tympany over the liver, which could be demonstrated by light percussion, was confirmative. A fluoroscopic examination led to the visualization of free air, which for practical purposes established the diagnosis of perforated ulcer.

After the perforation was discovered, operation was recommended but the patient refused to submit. It was difficult for him to understand why during the height of his pain operation was not suggested and now that he had apparently recovered laparotomy was being advised. No great amount of time or energy was lost in urging operation, since it was believed that the perforation had undergone spontaneous closure and that leakage had ceased. Nothing by mouth was permitted, fluids being furnished by the subcutaneous route. The patient was instructed to lie continuously on his left side.⁷ The patient continued to feel comfortable throughout the evening and slept fairly well that night, being awakened only two or three times for short periods which were not painful.

The following morning, August 4, the patient felt hungry and asked that he be served breakfast. On being informed that the orders were to withhold food and fluids by mouth for two more days he surreptitiously obtained and ingested a cup of coffee, two slices of buttered bread and a dish of prunes. Approximately an hour later he was seized by intense pain,

which, he stated, was similar in practically all respects to that of the preceding day. When examined shortly after the onset of this second attack of intolerable pain the patient was found to be diffusely rigid and tender. It now required no persuading to obtain his consent to operation.

At laparotomy, performed within an hour of the onset of the second severe pain a small amount of turbid fluid was encountered, as well as an injection of the upper abdominal peritoneum. There was a relatively large amount of fibrin deposited in the right hypochondrium. Covering the pyloric region of the stomach and hiding it from view was the edge of the liver. When this structure was raised, a hole 2 mm. in diameter in the anterior wall of the stomach near the pylorus was exposed. A thick layer of fibrin, which surrounded the perforation, was found on the serosa of the prepyloric region of the stomach and the opposing portion of the under surface of the liver. The amount and character of the fibrin suggested a perforation of at least several hours standing. The hole was sutured and covered by a flap of omentum. Recovery was uneventful.

The pathologic changes encountered appeared to be compatible with the sequence of events suggested by the clinical course: perforation into the free abdominal cavity at the time of the first attack of intense pain; limitation of leakage due to spontaneous closure of the hole by the overlying liver, indicated anatomically by the deposit of a thick ring of fibrin and clinically by cessation of pain and recession of signs of peritonitis; reopening of the hole due to separation of the liver from the gastric wall following the intake of food and recurrence of leakage indicated by the second attack of annihilating pain.

CASE 2—I. R., an automobile mechanic aged 23, was admitted to the Cook County Hospital, Oct. 7, 1931, with an entrance diagnosis of penetrating ulcer. He related that in March of the same year he began to suffer from mild postprandial pain of ulcer type which continued to trouble him periodically until July 11, 1931. Beginning with this date his former ulcer pain became more intense, persistent and refractory. October 5, two days before admission at 5:30 p. m., while straining in an attempt to tighten a bolt with a wrench, he experienced an extremely severe pain in the epigastrium.

Fig. 3 (case 3)—In this film taken two days after figure 2 the air is seen to have been completely absorbed. The patient had fully recovered spontaneously.

He felt, he stated, as though something internal had been torn loose. He doubled over and rolled from side to side, groaning continuously. After writhing about for fifteen minutes or so without relief, he sat astride the front seat of the automobile he was repairing. He remained practically immobile for approximately forty-five minutes, after which time he cautiously changed clothes. He then returned home on the street car, sitting bent forward with his arms crossed over his abdomen.

⁷ Vaughan, R. T. and Singer, H. A. The Value of Radiology in the Diagnosis of Perforated Peptic Ulcer. Surg. Gynec. & Obst. 49: 593-599 (Nov.) 1929.

⁸ The rationale of this procedure is given by Vaughan and Singer.

The walk to his house from the street car entailed a great deal of effort and was attended by sharp lancinating pain whenever he stepped from the pavement to the street. He retired that night without eating and experienced no difficulty in falling asleep. However, throughout the night he was awakened by sharp stabbing pains, which were readily relieved by change in position.

The following morning, October 6, he arose at the usual hour feeling weak but free from sharp pain. He ate a little corn meal and proceeded to return to work. He occupied himself with light tasks which, however, in his present state required a good deal of effort to perform. At noon he felt the old epigastric gnawing which led him to partake of a bowl of soup which afforded relief. At 2 p. m. the distress reappeared and soon became associated with nausea. Vomiting promptly ensued and while still straining he experienced a second attack of extremely violent upper abdominal pain which again suggested to him the sensation of his entrails being torn from their attachments. He squirmed about in an effort to obtain relief but soon adopted the supine position and remained there fearful of moving. After five hours had elapsed his employer returned and he ventured to move about. Guardedly he washed his hands and face and changed clothes, procedures which ordinarily took five minutes but which on this day because of pain of motion occupied a full hour. He again returned home on the street car and while riding became aware of an additional pain in the right lower quadrant. Sudden starting and stopping of the trolley led to stabbing pains throughout the abdomen. In walking from the street car to the house he was forced to exercise a great deal of caution since the slightest jolt led to knife-like pain. After arriving home he reclined but did not eat. Within a short time he became fairly comfortable and remained relatively free from pain unless he moved suddenly.

At 11 p. m., thinking that he required a bowel movement, the patient took half a bottle of effervescent magnesium citrate. Within a short interval he was seized for the third time by most excruciating pain, which was perhaps even more intense than that of the two previous attacks. At least it was more persistent and on this account at the end of an hour's intolerable agony he summoned a physician. The patient noted himself that the abdomen was "firm as a rock." The physician diagnosed appendicitis, administered a hypodermic and advised hospitalization. The narcotic led to some amelioration of the pain but not complete relief. The patient entered the hospital, Oct. 7, 1931, at 2:30 a. m., at which time his temperature was 99.8 F., his pulse rate 100, and the respiratory rate 28. The abdomen was scaphoid. There were noted slight tenderness and moderate rigidity of the right upper quadrant. The peristaltic sounds were normal in quality but diminished in quantity. The white count was 16,000. The admitting physician, although suspecting that a perforation had occurred, could not reconcile this opinion with the paucity of physical signs. He decided, therefore, to admit the patient with the diagnosis of penetrating ulcer. During the night the patient was awakened at intervals by pain of a sharp nature located on the right side. In the morning he awoke feeling quite comfortable. Since the house physician who admitted the patient had failed to leave orders to the contrary, breakfast was served him at 7:30 a. m.

For breakfast the patient drank a few sips of coffee and ate a small portion of cooked cereal. Immediately following the meal he suffered a fourth attack of excruciating pain. He again doubled over writhed about in agony and broke out in a profuse, cold sweat. Examination by the senior intern shortly following this episode indicated that the right rectus was rigid and prevented satisfactory palpation of the underlying structures. I saw the patient for the first time at 11 a. m. that morning (October 7), at which time I elicited the foregoing history. The patient appeared to be quite comfortable and stated that he was but when asked to move he did so slowly and cautiously. He avoided deep inspiration and after talking for a period of time he would become dyspneic and be forced to pause. The shortness of breath was indicated also by dilatation at times of one or both nostrils during inspiration. Physically the patient presented no distention and in fact the abdomen was scaphoid. The right upper quadrant was moderately tender on deep pressure elsewhere the tenderness was

only slight. There was no actual rigidity, but muscle defense was noted when deep pressure was made in the right hypochondrium. The temperature was 99.8 F., the pulse and respiratory rates 96 and 24, respectively. Fluoroscopically (fig. 1) a very thin zone of radiolucence could be seen in the upright but not in the left lateral position.

The diagnosis of perforated peptic ulcer with intermittent leakage was made and operation advised. An upper right rectus incision was recommended, since the signs of peritonitis corresponded in location with a duodenal rupture. When the peritoneal cavity was opened a small amount of free fluid which was turbid was found. Throughout the right upper quadrant thick fibrin was deposited. The under surface of the filled gallbladder was in apposition with the anterior wall of the first portion of the duodenum. Raising the gallbladder led to the exposure of a 2 mm perforation surrounded by a thick gelatinous deposit. Palpation indicated that the wall of the duodenum was indurated and thickened for a distance of 1.5 cm radially. The under surface of the gallbladder was covered by an edematous fibrin similar to that deposited on the duodenum about the perforation. In addition to fresh fibrin there were veil-like strands in the right hypochondrium, which appeared to be older and in the process of early organization. The perforation was sutured with silk and covered by an omental flap. The patient made an uneventful recovery and was discharged October 18, feeling quite well.

CASE 3—M. B., a white man aged 47, was admitted to the medical service of the Cook County Hospital, April 16, 1932, at 7:40 p. m., with a diagnosis of penetrating peptic ulcer. He stated that for eight years he had suffered periodically from a rhythmic distress. This was of a burning nature, located just beneath the tip of the xiphoid process and possessed the characteristics generally ascribed to an uncomplicated ulcer. The night before entrance the patient felt nauseated and attempted to vomit but did not succeed. The following day, April 16, he felt well until 4 p. m., when, while sitting in a rocking chair, he experienced sudden, annulating pain. At the onset the patient felt as though his entire abdominal contents were being pulled asunder but within a few seconds the pain became sharp and knife-like. He was helped to bed, where he writhed about and groaned in extreme agony. A physician, on being summoned, responded within twenty minutes of onset. He found the upper abdomen boardlike and tender and advised immediate hospitalization. A police ambulance was ordered and arrived ten minutes later.

The patient had difficulty in dressing on account of the pain incurred by movement. He found it necessary to hold himself rigid (immobilize the abdominal muscles) in order to avoid the stabbing pain occasioned by motion. The ride in the ambulance was extremely distressing, since even the slightest jar provoked sharp, lancinating pain. When the patient reached the hospital, an hour or so after the onset of the intense pain, he was placed on a hospital cart, where he remained for fifteen minutes before he was examined. When lying quiet the patient felt rather comfortable and when questioned by the admitting physician made no complaint of pain. After a cursory examination the physician decided he was dealing with a "penetrating" and not a perforated ulcer. He gave the patient the option of remaining or returning home. The patient, who was feeling greatly improved, chose to leave and was given a prescription for a mixture of alkaline powders.

As the ambulance on its return was approaching his house, the patient experienced a second attack of violent pain, which was quite similar to the first. He did not return to the hospital then and there, since he expected to obtain relief from the medicament prescribed. With a great deal of effort and agony he managed to climb a flight of stairs. He returned to bed and sent the prescription that he had received at the hospital to a nearby drug store to be filled. The pain, however, was so intense that he was unable to wait until the messenger with the prescription returned. He requested a neighbor who owned an automobile to transport him to the hospital about fifteen minutes after he had returned from there. The second trip occasioned more suffering than the first, each bump in the road producing a sharp cutting abdominal pain.

After the patient had waited in the entrance room of the hospital for a few minutes, the pain moderated considerably.

He was again briefly questioned and hastily examined by the same physician who admitted the patient with a diagnosis of penetrating ulcer and assigned him to a medical service. In the ward the patient's temperature at 9 p. m. was found to be 99.6 F., the pulse 76 and the respirations 24. The nurse's notation made at this time read, 'Complains of pain in abdomen but does not appear acutely ill.' The resident physician, who was summoned on the patient's arrival in the ward observed that there was moderate tenderness and rigidity in the epigastrium and right upper quadrant slight tenderness throughout the abdomen and a positive peritoneal reflex. Although the history pointed to a ruptured ulcer the resident felt that the excellent general condition of the patient and the lack of apparent agony were incongruous. He therefore likewise assumed the presence of a penetrating ulcer rather than an actual perforation.

The patient without medication promptly fell asleep. At 1 a. m. it was noted by the nurse that his face was flushed. The rectal temperature was found to be 102.4 F., the pulse rate 92 and the respiratory rate 22. At 5 a. m. the temperature was 100.4 F., the pulse and respiratory rates 88 and 22 respectively. The temperature at 8 a. m. had dropped to normal the pulse rate had decreased to 60 and the respiratory rate was 18. At relatively long intervals throughout the night the patient was awakened by sharp pain. He would change position and almost immediately fall back to sleep. After 8 o'clock the following morning (April 17) the patient experienced no pain unless he moved suddenly. When first seen by me about noon of April 17 which was the day following admission the patient had already received a glass of water and several doses of cream and milk and Sippy powders. He was sitting in bed reading a newspaper without any sign of concern or discomfort on his countenance. Slight tenderness was elicited in the right upper quadrant, associated with muscular defense when deep pressure was made. Peristaltic sounds were normally present.

The history and clinical signs pointed directly to a perforated ulcer with the intermittent leakage. In order to determine if possible the correctness of the diagnosis a fluoroscopic examination was made. A collection of free intraperitoneal air was visualized and was assumed to have escaped from the stomach. As plate service is not available on Sunday, no film was obtained. The diagnosis of a perforation being established the question as to the patency of the hole arose. It was quite apparent at this time that no leakage had occurred subsequent to the time the patient had entered the ward. As the correct diagnosis was not made on admission the patient had received fluids and powders by mouth in spite of which no pain was experienced. It was safe to assume, therefore that the hole was effectually closed. On this account operation was deemed unnecessary and the patient was treated conservatively. In order to prevent as far as possible the reopening of the hole and subsequent leakage, the patient was ordered to lie on his left side and take nothing by mouth. Fluids were furnished rectally and subcutaneously.

The patient slept well that night except for an occasional mild pain. The following day he complained of hunger and stated in reply to a question that his pain was very slight. The temperature, pulse and respiratory rates were normal and remained so throughout the rest of the patient's stay in the hospital. After fluids and nutriment by mouth had been withheld for three days, the routine Sippy treatment for ulcer was instituted. In the meantime the radiologic examination (fig 2) made on April 18, two days after onset, showed a diminution in the amount of air as compared with the fluoroscopic observation of the previous day. April 20 four days after the acute manifestations, no free air was demonstrable (fig 3). The further course was entirely uneventful. The patient was discharged, May 5, nine days after onset, on a modified Sippy diet. He failed to return for further observation.

COMMENT

Knowledge of the clinical behavior of a perforated ulcer with intermittent leakage is essential if mistakes in diagnosis and management are to be avoided. A number of "medical" disturbances, including gall-

bladder disease, penetrating ulcer, coronary thrombosis, tabetic crises and diaphragmatic pleurisy, are erroneously diagnosed. Fortunately the mistake although embarrassing, is not as a rule very costly. Should the unrecognized perforation be securely closed, the recovery will generally occur in spite of food intake. If, on the other hand, owing to the administration of food, adhesions that originally sealed the hole are torn and further leakage is permitted the symptoms and signs are usually sufficiently definite to lead to a diagnosis of "surgical abdomen" and to operation. As the true cause of the symptoms under these circumstances is not known, the initial incision is often improperly placed. This occurred in a recent case of perforated ulcer which I saw for the first time following laparotomy. The history was that of recurrent attacks of intense pain and the physical signs were those of tenderness and muscle defense on the right side. Acute appendicitis was diagnosed and a right lower quadrant incision made. It was therefore necessary to make a second incision in the upper part of the abdomen to deal with the perforation. Fortunately, the patient made a good recovery.

The diagnosis can generally be made by eliciting a careful history. The occurrence of a periodic, rhythmic pain of ulcer character over a period of months or years is frequently obtained if pertinent questions are asked. An account of violent pain indicating the occurrence of perforation followed by mild postoperative symptoms is usually forthcoming but often requires adequate interrogation. It is necessary to have the patient relate the story minute by minute and when this is done it is surprising how accurately even patients with limited intelligence can recall each step in the development of the illness. The x-rays are often of value in establishing the diagnosis by permitting visualization of free air. However, the absence of a spontaneous pneumoperitoneum particularly in the cases with limited leakage is not uncommon⁹ and does not militate against the diagnosis of perforated ulcer.

The treatment of cases with intermittent leakage follows the rules accepted for ruptured ulcer in general. Since there is a tendency toward spontaneous closure in most of the instances presenting intermittent leakage those principles recommended for the treatment of forme fruste perforations¹⁰ are particularly applicable. To avoid misunderstanding it is again emphasized that laparotomy is resorted to in all cases of perforation in which the patient is seen early. Only in those instances seen relatively late, when spontaneous closure of the hole can be established with a reasonable degree of certainty, is operation not employed as a routine. Whenever the slightest doubt exists as to the patency of the perforation, operation is insisted on.

SUMMARY

In addition to the classic and forme fruste types of perforated peptic ulcer there is a third variety which is characterized by intermittent attacks of extremely violent pain. The atypical symptomatology is presumed to be due to intermittent leakage occasioned by alternate spontaneous sealing and reopening of the perforation. The reopening frequently follows the intake of ingesta which is not prohibited since the true condition

9 Vaughan R. T. and Singer H. A. Further Observations on the Value of Radiology in the Diagnosis of Perforated Peptic Ulcer. *Am. J. Surg.* 21: 392-396 (Sept.) 1933.

is seldom recognized. At any time following recovery from the first attack of pain spontaneous closure may fail to occur and the picture of a classic perforation supervene. In two of the three illustrative cases described, operation was performed after the second and fourth attacks of pain, respectively. In the third case spontaneous recovery ensued following the second outbreak of annihilating pain. Knowledge of the clinical manifestations of a perforated ulcer with intermittent leakage is necessary to avoid errors in diagnosis and treatment.

INFLUENCE OF TYPE OF CURRENT ON POSTOPERATIVE COMPLICATIONS IN TRANSURETHRAL SURGERY

JOHN R. CAULK, M.D.

AND

JOHN F. PATTON, M.D.

ST. LOUIS

It was over a decade ago that the attention of American urologists was summoned to the efficacy of transurethral surgery for the removal of many of the large prostatic obstructions. Throughout these years they have been repeatedly advised of the ever increasing value that the Caulk cautery punch seemed to afford for the removal of such obstructions. This operation has fulfilled the obligations that were demanded of it as an acceptable surgical procedure, namely, simplicity of operative technic, applicability, freedom from complications and disabling sequelae, negligible mortality rate and, above all, satisfactory and lasting results.

The results of this operation have been detailed specifically on innumerable occasions and shown to be productive of excellent results in at least 80 per cent of all obstructions. Last year one of us¹ reported an analysis of 781 cases. In this series there were 100 very large prostates that were removed by this method, 70 per cent of these patients were completely relieved of obstruction for from three to ten years, and 22 per cent were sufficiently comfortable to refuse further operative relief. Throughout the whole series of cases attention has always been called to the necessity of repeat operations in order to spare the patient prolonged instrumentation and to protect him from the creation of too much raw surface for absorption and hemorrhage, as well as to allow nature to aid in the process of resolution through drainage. These factors still appeal to us as fundamental for the proper conduct of any type of transurethral prostatic operation.

The essential requirements for transurethral surgery are

- 1 The same preparation as for prostatectomy
- 2 A sincere respect for the urethra and an aim to protect it from unnecessary trauma
- 3 The selection of the best physical agent for the removal of the obstruction and the proper administration of this agent
- 4 Vigilant postoperative care

Our continued faith in and deep regard for this type of surgery makes us exceedingly anxious for its proper

development. It is gratifying to observe the tendency of urologists at the present day to adopt transurethral surgery in an increasing percentage of cases. The inclination at present is to employ various types of high frequency currents for the technical extraction of tissue. Whatever method of removal through the urethra is employed, it seems now to be definitely proved that permanent cures can be effected, and in this paper the late results will not be considered. The influence of the method of removal of tissue with reference to its effects on postoperative complications and on the mortality rate will be discussed.

Urologists find themselves today exceedingly disturbed concerning the whole problem of handling the obstructing prostate. This current surgical restlessness has resulted from a sudden epidemic of instruments and currents which have been thrust on them and placed, in many instances, in the hands of those who were entirely unprepared to cope with their intricacies. The child is showered with an intoxication and it is not yet known what the child's resistance will be.

It must be definitely understood that any type of transurethral prostatic removal is a delicate, highly technical procedure, requiring the utmost skill and thorough training on the part of the surgeon and that every sincere effort should be made to obviate the dangers that are lurking around in case of improper application. Unless the profession promptly comes to the realization of these important features, this type of surgery, which should have a brilliant future, will not survive.

Urologists are thoroughly cognizant of the necessity for accurate preliminary treatment and detailed postoperative care but as yet are without agreement as to the most satisfactory method of operative application. We have felt for a long time that the removal of obstructing tissue with the cautery punch was far safer than the extraction with high frequency currents. The cautery seems to remove the tissue effectively and to obviate hemorrhage and absorption through mild coagulation, it is not attended with complications that can be ascribed to the cautery, whereas the high frequency currents appear to possess natural inherent dangers and seem to create certain postoperative complications that can definitely be attributed to the effects of these currents. In order to verify this, and with a hope of protecting transurethral surgery from any unnecessary hazards, we have undertaken two phases of this important problem: the first, an experimental and clinical study of the effects of various high frequency currents and the actual cautery on experimental mediums, animal and human tissue; the second, a compilation of statistics secured from the members of this association relative to the effects of these methods on the postoperative course and the mortality rate.

EFFECTS OF VARIOUS HIGH FREQUENCY CURRENTS

The various electric currents have been used rather promiscuously for the removal of prostatic obstruction, the operators in most instances have been led to the belief that they possessed no dangerous qualities, were practically harmless, and certainly created no deleterious distant effects on tissue. Most urologists have been fascinated by the manner in which tissue can be removed by high frequency resection, but few have stopped to analyze any of the inherent potential dangers in the manipulation of these high tension currents, and most of them have been entirely ignorant of their physical characteristics. It was only after a late sec-

ondary hemorrhage or a severe urinary sepsis or some other unpleasant sequel of an operation that had gone nicely, that they began to puzzle and wonder what branch of technic had been responsible for this consequence. The manufacturers had said that there was no heat except at the site of the burn. It was therefore supposed that something in the manner of manipulation,

Punch was heated from 5 volts

too much coagulation or too great a rapidity of the strokes had been responsible for this eventuality. Usually, however, a satisfactory explanation was not at hand. It seems therefore propitious that a more thorough knowledge of the fundamental workings of these currents be undertaken.

We were fortunate in securing Mr. Wilbur Harris of the Department of Physics to work with us for a period of nearly four months. During this time the effects of the various currents and the actual cautery were tested on experimental mediums, heart muscle, fat, meat, and animal and human tissue, particularly the prostate. The results of these experiments were reported in detail before the American Association of Genito-Urinary Surgeons in May. It was promptly determined that the deleterious effects of the various high frequency currents that are employed for the removal of prostatic tissue resulted from heat and that electrolysis and destruction of cells through electrical vibration played an insignificant role, if any. In order to determine the heat effects in tissue at definite distances and with definite current values and time exposures, the standard thermocouple galvanometer combination was used. The thermocouple was placed at different distances in the tissue, away from the actual site of application of the current or cautery, and the temperatures were recorded at repeated intervals following the applications.

In the experiments, an effort was made to mimic as closely as possible a typical transurethral operation, not only were the amount of current and the time of application regarded but the proper cooling time was allowed and the tissues were constantly flooded with water. In actual experiments on the prostate, the thermocouple was placed into the prostate through the perineum by means of trocars in a manner similar to the application of radon seeds and in the suprapubic operations both animal and human, the thermocouples were placed at measured distances in the gland away from the site of the burn. It was shown that with the high frequency currents which were usually employed, whether the gap or the tube machine, definite elevations of temperature were produced in the mediums or tissues away from the point of burning, and the degree of heat varied according to the distance, the current value and the time

of application, and depended not on conduction but on production in tissue as it came through between the two electrodes and concentrated at the point of burning. With cautery applications or removals, on the other hand, no such elevations of temperature were registered after repeated applications. For instance, at 0.8 cm. away from the site of the burn, it required seven applications of the cautery heat for three seconds each to reach an elevation of 0.03 degree C, whereas with the high frequency current of only 500 milliamperes, at this distance and with the same application time, a 132 degree elevation was recorded. Throughout the experiments it was found that high frequency currents often generated high temperatures. At 0.4 cm. away from the point of application with the use of a 900 milliamper current value, applied for two three second applications there was produced in gelatin a 25 degree elevation of temperature. The same high elevations of temperature were persistently recorded in the prostates of animals and man following the application of these electric currents.

Operators have been seriously deceived by the appearance of the tissue within the loop of the resection apparatus. Owing to its good preservation, it has naturally been thought that there could be no excessive heat in the tissue left behind. This is fallacious for the reason that the tissue within the loop is beyond the heat path between the two electrodes and receives its heat only through conduction from the loop, whereas the remaining tissue beneath the burn is exposed not only to the conduction heat from the loop but more particularly to the concentrated heat between the electrodes.

EFFECTS OF THE ACTUAL CAUTERY

In no instance did we find, even after repeated applications of the actual cautery to the various tissues or with the cautery punch removals of prostatic obstruc-

tion, an elevation of over 3 degrees. Table 1 expresses this comparison admirably. At a distance of 0.4 cm. from the point of application, it is noticed that following an application for three seconds of a 900 milliamper current value there was nearly a 9 degree rise of temperature, the second application produced 19 degrees, whereas with the cautery punch applied to the same surface under the same condition it required four applications to reach 0.1 degree and nine applications to produce 2.9 degrees.

Table 2 shows the temperatures recorded during a prostatic resection operation in which the high frequency current was employed. The patient had a bilateral hypertrophy. The thermocouple was inserted into the prostate through the perineum. Resection was done chiefly on the lateral lobes, mostly away from the site of the thermocouple. It is noticed in the fourth

of a centimeter away which are entirely incompatible with the life of cells, the thermal death point of tissue being from 45 to 47 C.

HISTOLOGIC STUDIES

We have made numerous histologic studies at different intervals of the tissue remaining after the application of high frequency currents, and it has been uniformly observed that there are three definite zones produced:

1 Coagulation necrosis

2 A zone of fragmentation in which the cells have lost their staining qualities and are broken up, in many instances. The nuclei are pyknotic, and the cytoplasm shows vacuolization and fragmentation. This zone shows copious hemorrhage throughout the tissue.

3 A more or less normal zone, but the cells show desquamation and evidence of shrinkage.

It is this deep heat effect that is evidently responsible for many of the late sloughs and the erosion of vessels that creates the tendency to secondary hemorrhage and sepsis. These deep effects are never observed following cauterization.

It was also determined that the paths of heat throughout the body follow the deep vessels and the highly vascular tissues and possess a selective effect for electrolytic fluids, for instance if the rectum is crushed with a clamp and exudate is allowed to accumulate, the heat will concentrate on this point even though the electrodes were not in the vicinity. This should have a definite bearing on the clinical application to resection and signifies the necessity for a thorough understanding of the bowel condition at the time of operation. A constipated stool, infected fissures or hemorrhoids would tend to concentrate heat and might enter into the creation of a recto-urethral fistula. In many of the experiments it was noted that high elevations of temperature were produced in the rectum, at times more pronounced than in the prostate.

The conclusions to be deduced from these experiments are that high frequency currents produce heat in tissues away from the site of actual burning, often

from the last line and in the last line, when the current applications were made near the median portion, that the temperature elevations were exceedingly high. It is fair to assume that these elevations were produced in other portions of the gland but could not be recorded because of the distance from the thermocouple.

Table 3 shows temperatures recorded in the human prostate following suprapubic exposure with the thermocouple placed in the gland at a distance of 2 cm from the site of application of current. At this distance, temperature elevations of from 8 to 12 degrees are recorded following very short applications of current. The lower part of the table shows an elevation of 26 degrees in the third line, at a distance of more than 1 cm from the source of application with a high current value but with a short application of only a second and a half.

Table 4 gives temperature records produced during the process of a cautery punch operation. With the thermocouple in the prostate placed through the perineum and exactly in the same manner and apparently at the same distance as for the high frequency measurements, the highest rise of temperature was less than 2 degrees.

The slight heat elevations following the cautery applications are due entirely to conduction, that is, they extend from the point of application down into the tissue, but the high frequency currents are entirely different; the heat in tissue is produced as the heat waves come from one pole to the other. It was furthermore demonstrated that the low coagulating currents, which apparently cause more visible surface necrosis, generate far less heat in the tissue. For instance, with the usual coagulating current of 300 milliamperes or about one third of the cutting type, the amount of heat generated in the tissue is one ninth of that produced by the corresponding cutting current. In most instances following the application of the high frequency current, temperature elevations have been recorded even at a distance

beyond the thermal death point of the tissue, that cautery heat does not penetrate to such depths, its only heat resulting from conduction and being superficial, that the coagulation currents produce far less heat in tissue than the cutting, that the heat generated by high frequency currents is accumulative and that hence a proper cooling time should always be given between current applications, in order to preserve as closely as possible the normal blood flow through the prostate. This normal flow was determined in our experiments

to be 0.68 Gm of blood through a cubic centimeter of tissue per minute. With this in mind, it is highly essential in removing prostatic tissue with these currents to use currents of as low value as possible, to apply them quickly, to move from one place to another, never repeating the application at the same place, and, in case

of hemorrhage, to use low coagulation. Extensive resections requiring excessive application of current is to be condemned, since the penetrating heat produced near the outer surface of the prostate might lead to late sloughing and erosion beyond the confines of the gland and produce extravasation, bladder and urethral ruptures and possibly recto-urethral fistulas.

TABLE 6—Total Number of Resections (1,073)

196 operators only 7.67% cases had definite data concerning hemorrhage	
Total hemorrhage	917 10.1%
Primary mild	272
Primary, severe	161 2.1% of total
Cystotomy necessary	8 10.2% of hemorrhage
Secondary mild	278
Secondary severe	106 1.3% of total
Cystotomy necessary	20 9.4% of hemorrhage
Total cystotomies required in 1.7% of all cases	
Severe hemorrhages primary and secondary 3.4% of all cases and 3.4% of all hemorrhages	
Recto-urethral fistulas	5
Temporary incontinence	113
Permanent incontinence	33
Urinary sepsis mentioned by 5% of the operators and as a cause of death in 91 cases four times as many as the punches	
Extravasation	7
Stricture of urethra	4
Perivesical abscess	4
Phlebitis	2
Rupture of bladder	1
Peritonitis	1
Gangrene of bladder	4
Perforation of bladder	2
Rupture of diverticulum	1
Ischio-rectal abscess	1
Perineal abscess	1
Triangular injury	1
Pelvic abscess	1
Torn bladder neck	1
Peri-urethral abscess	1
Electrocution	1
Mortality (deaths 392)	3.74%

It seems certain also that the repeated applications of heat to the region of the internal vesical sphincter could devitalize the muscle sufficiently to create incontinence of urine, and, finally, that the slough produced by excessive burning might be productive of necrosis of a sufficient extent to cause late secondary hemorrhage and urinary sepsis.

In dealing with the large obstructions, it is therefore obvious that repeat operations rather than extensive single stage procedures must be employed for the sake of safety. We have demonstrated with the Caulk punch operation, on frequent occasions, that large amounts of obstruction can be easily removed at one operation, but the postoperative course is not as smooth as in the less radical removals. In extensive resections two of the important principles of surgery are ignored, namely, the insult to the urethra through prolonged instrumentation and the creation of an extensive raw surface with inadequate drainage, such as can be afforded by an indwelling urethral catheter. In the tremendous prostates which we feel should demand repeat operations, considerable time is often necessary to effect a proper functional result. If the subject is a poor surgical risk it is particularly important to minimize each procedure, and the time element must play no role. In a younger subject, who is physically sound, where time may be important, we should prefer to do a prostatectomy.

In order to compare the effects resulting from the various operative procedures and in an effort to determine whether the experimental results possessed a true clinical significance, we have tabulated data relative to

TABLE 7—Serious Complications Which Caused Death Aside from Ones Already Mentioned*

Punch		Resection	
Total punch death	81	Total resection death	30
Sepsis	20	Sepsis	91
Embolus	1	Embolus	1
Apoplexy	2	Apoplexy	7
Cardiac	6	Cardiac	24
Shock	2	Shock	19
Septicemia	2	Septicemia	8
Pyelonephritis	11	Pneumonia	20
Uremia	2	Uremia	21

In comparing the two series it is noteworthy that embolus occurred almost ten times as frequently following electrical resection. Uremia resulted over five times as commonly following resection as it did with the punch operation which unquestionably testifies to the lack of proper preparation in many of the cases in which operation has been performed by the resection method and urgently signals the strict necessity for following in the precepts of urology in the way of preliminary preparation.

The complications that have ensued from these different operations performed by numerous operators throughout the country. We are indebted to the men who have furnished us with their operative material.

COMPARATIVE STATISTICS

Questionnaires were sent to more than 800 urologists, and replies were received from 244. These 244 operators have performed an aggregate of 15,488 trans-urethral operations. Of these, 7,415 were performed with the various punch techniques and 8,073 with high frequency resections. The various punch operations were performed by 159 operators, 196 had done the resection, and 141 had done both.

The total number of punch cases, 7,415, were done chiefly by the Young, the Caulk and the Braasch-Bumpus method, that is, the cold cutting, the cautery, and the preliminary coagulation with removal afterward. There were eighty-one operators who used the Caulk cautery punch method, fifty-four of whom used it to the exclusion of all others. The cautery punch was used in 2,774 cases. Many of the reports stated that the punch had been used but did not state the type of instrument utilized. Of the 8,073 resections, 5,560 were done with the McCarthy instrument, 855 with the Stern Davis, and the remaining 1,658 were done by various

high frequency methods, but the operators did not designate the method employed.

From this large series of cases, we have tabulated data with reference to postoperative complications resulting from the different types of transurethral surgery and have noted particularly hemorrhage, primary and secondary, the number of cystotomies required to control bleeding and the incidence of urinary sepsis, incontinence and other serious complications. There is a general comparison of the resection operations and the various punch procedures as well as a study of the complications resulting from the two chief types of electrical appliances, namely the gap and the tube machines, a comparison of the postoperative course of the punch and the resection cases done by operators who are using both techniques, and finally a statistical analysis of the postoperative complications of the patients on whom the cautery punch has been used.

In surveying tables 5, 6 and 7, one is immediately impressed with the fact that postoperative hemorrhage occurs much more frequently with the resection instruments than with the punch, the ratio of severe hemorrhages being almost two to one. Cystotomy to control the bleeding was required twice as often for the resections. Permanent incontinence resulted in an astounding

TABLE 8—Comparison of the Complications Resulting from the Two Types of Electrical High Frequency Resections

Gap Machine		Tube Machine	
106 operators	294 cases	144 operators	1,440 cases
Severe hemorrhage	90 2.8%	Severe hemorrhage	97 6.7%

Cystotomy necessary	24	Cystotomy necessary	30
Secondary severe	3 1.1%	Secondary severe	30 2.0%
Cystotomy necessary	9	Cystotomy necessary	15
Total cystotomies required	10%	Total cystotomies required	3.0%
Rectal fistulas	3	Rectal fistulas	2
Temporary incontinence	48	Temporary incontinence	42
Permanent incontinence	1*	Permanent incontinence	11
Sepsis	84 2.8%	Sepsis	121 8.3%

percentage following resections, and only one case was reported following the punch technic. Urinary sepsis was mentioned by two and a half times as many resection operators as it was by the punch operators. Other severe complications such as extravasation, rupture of the bladder, and abscess formations, were reported thirty-nine times with resection and in nine instances with the punch. It is interesting to note that five rectourethral fistulas were reported as complications with the resection operations and we have been told of many more, and not a single one occurred with any of the punches. These severe sequelae unquestionably result from the penetrating heat deep in the tissues, which has been previously described, occur only with the electrical resections, and serve as a definite record of the dangers of the electric currents unless properly appreciated and definitely controlled. The mortality rate in the two series reveals that death occurs more than three times as frequently with the resection as it does with the punch. We are thoroughly aware that some operators have reported large series of cases with few attendant postoperative complications and a very low mortality rate, but most of these operators, in the beginning, had a death rate entirely disproportionate to what should be expected with this type of surgery. There is no operation that should require such a tremendous sacrifice in order to perfect a technic.

A comparison of the two types of machine (table 8) discloses that severe hemorrhage occurred almost three

times as frequently with the tube machine. Temporary and permanent incontinence occurred much more frequently, and sepsis accompanied the tube machine three and a half times as frequently as with the gap.

In a comparative study of the results secured with the punch and resection, performed by operators who

TABLE 9—A Comparison of the Results Secured with the Punch and Resection by 141 Operators Using Both Methods

Punch		Resection	
Number of cases	6,005	Number of cases	4,885
Primary hemorrhage	22 5.5%	Primary hemorrhage	292 6.0%
Primary mild	21 7.0%	Primary mild	147 59.0%
Primary severe	84 2.0%	Primary severe	145 59.0%
Primary cystotomy	23 or 0% of total cases	Primary cystotomy	6 or 1% of total cases
10.0% of primary hemorrhages		22.0% of primary hemorrhages	
Secondary hemorrhages	154 2.5%	Secondary hemorrhages	322 6.5%
Secondary mild	117 76.0%	Secondary mild	277 74.0%
Secondary severe	37 24.0%	Secondary severe	85 26.0%
Secondary cystotomy	13 or 0.2% of total cases	Secondary cystotomy	7 or 0.7% of total cases
8.4% of secondary hemorrhages		10.2% of secondary hemorrhages	
Of the total number of cases 0.6% had severe secondary hemorrhage		Of the total number of cases 1.8% had severe secondary hemorrhage	
Mortality (deaths 58) 0.9%		Mortality (deaths 231) 4.7%	

were using both (table 9), some interesting data may be observed. The occurrence of primary hemorrhage was about the same except that severe primary hemorrhage occurred twice as frequently with the resection, and cystotomy was required to control primary bleeding more than twice as often. Secondary hemorrhage on the other hand, occurred almost three times as often with the resections as it did with the punches and the mortality was more than five times as great with the resection, being 4.7 per cent with resection and only 0.9 per cent with the punch technic. This surprisingly high mortality following electrical resection operations should make one pause and appreciate the seriousness of this type of surgery. Such a mortality is higher than should occur with prostatectomy properly performed. It is indeed gratifying to those who are using the punch technic to see that in more than 6,000 cases there is a comforting mortality of less than 1.0 per cent.

In table 10 an analysis of 2,774 cases done by the cautery punch is detailed. The total hemorrhages

TABLE 10—Postoperative Complications of the Cautery Punch

Cautery punch cases	2,774
Total hemorrhage	189 6.8%
Primary mild	121
Primary severe	36 1.3%
Cystotomy necessary	10
Secondary mild	24
Secondary severe	8 0.28%
Cystotomy necessary	2
In other words only 1.6% had troublesome hemorrhage	
Total cystotomies required in only 0.4% of these cases	
Temporary incontinence	11
Permanent incontinence	1
Urinary sepsis	42 1.5%
Stricture of urethra	1
Mortality	0.9%
In this series postoperative complications of any consequence amounted to only 3.6%	

occurred less frequently than with the combined punch procedures and almost half as commonly as with the resections. In only 1.6 per cent of all cases did troublesome hemorrhage occur, and cystotomy was required in only 0.4 per cent of the cases almost half as often as with the total punch group and one fifth as commonly as with the resections. Other serious complications were

negligible. Only 15 per cent of the patients had urinary sepsis, and only 3.6 per cent of the total number of cases showed any complications of a serious nature. The accompanying mortality rate was 0.9 per cent.

COMMENT

It is thus evident that the smallest incidence of hemorrhage, the slightest demand for cystotomy, and the fewest number of complications occurred following the Caulk cautery punch operations performed by numerous operators. The superficial heat produced by the punch is sufficient to minimize hemorrhage and sepsis and does not produce the troublesome complications that accompany the various types of electrical resections.

It is without question that the high frequency currents possess inherent dangers which must be thoroughly appreciated, and even when appreciated are often beyond human control. Therefore, if transurethral surgery is to be safeguarded such currents must be materially modified or discarded.

There can be no doubt therefore from the testimony afforded through the experimental investigation as well as the accumulated data, that the removal of prostatic obstruction through the urethra is more safely performed by the punch procedure, by means of the cold cutting followed by coagulation by preliminary coagulation supplemented by punching or by the cautery punch. The evidences afforded through this analysis prove to us conclusively that the cautery punch is the safest of all.

It is still our belief that the original cautery punch offers the quickest, safest and most effective method of removing prostatic obstruction. The vision obtained by reflected light reveals the natural orifice and affords an unmistakable picture. For some reason, operators have felt a timidity in relying on this type of vision but this is due entirely to inexperience. Most of the ideas have been purely impressionable rather than actual.

MODIFICATION OF PUNCH

In order to satisfy the demand for cystoscopic visualization and irrigation, a modification of the punch instrument which embodies a cautery current and telescopic visualization, has been developed.² We submit this instrument for consideration. The shell of the instrument consists of an outer sheath which carries a small sealed channel down to the punch-shaped fenestra for the McCarthy Foroblique telescope and light. This channel imparts a slightly oval shape to the sheath, which is also equipped with a beak similar to the former punch and which allows easier introduction into the bladder than straight instruments.

The working element embodies a platinum-iridium knife in the form of three fourths of a circle connected to metal electrodes. The absence of a complete circle allows the knife to slide over the telescope and light and gives vision of the movement of the knife during the entire cut.

The metal electrodes, which correspond in shape to the knife, are prolonged backward out of the sheath and contain large irrigating and exhaust ducts, through the former of which a fulgurating electrode may be inserted to control hemorrhage, should this arise.

The connection to the transformer is effected through a terminal on the working element which allows connection on either the right or the left side, as convenience demands.

This connection also acts as a handle to push the working element through the fenestra.

The current is supplied by a stepdown transformer, delivering a low voltage high amperage current. This transformer is equipped with a foot switch that does away with the need of another assistant and gives the operator complete control during the operation.

After the instrument has been inserted and the working element has taken the place of the obturator, the operator is accorded a view that allows no mistake in his orientation of the piece of tissue that will be removed when he sends the blade home. Thus, before him is the hollow end of the sheath at the end of the fenestra and filling into the fenestra may be seen the lobes of the prostate as the sheath is rotated. The offending lobe is selected and the sheath raised or lowered, whichever the case may be to bring the portion of tissue to be excised more firmly into the fenestra, just as in the original punch.

With the water running the operator pushes the blade up until it touches the entrapped gland. While still exerting a moderate pressure on the working element, the surgeon steps on the foot switch and immediately feels the knife begin to travel through the tissue, and in approximately two seconds he recognizes the click as the blade enters the distal end of the fenestra, signaling that the cut is complete and to release the foot switch.

If he has been observing the procedure through the telescope he will have seen the blade advance to meet the tissue, hesitate a moment as the foot switch is depressed and then see the edges of the blade advance rapidly toward the distal end of the fenestra. As the blade moves forward it is possible to see the tissue in the fenestra drop free of the gland as it is cut, and the free tissue in the slot after the cut is terminated.

The water is then shut off to avoid washing the excised tissue from the fenestra and the working element removed, which contains the loose piece of tissue.

The ability to cut under water with the cautery current has been a gratifying feature of this instrument. It cuts as quickly and as cleanly as any of the electric currents, and visualization is not disturbed by bubbles. In many instances the blade can be observed throughout the incision, and the inspection with this instrument has been more complete than with any other that we have employed.

If there is a bleeding point, the fulgurating electrode may be pushed forward and allowed to protrude from the slot and be brought against the bleeder under excellent visualization. This act is facilitated by the to and fro movement of the knife blade which acts as a deflector. As a matter of fact, in the few instances in which we have observed bleeding it has been controlled by the to and fro movement of the cautery blade over the site of the hemorrhage.

In actual operation there has been very little hemorrhage which has been readily controlled, and the field of vision has at all times been clear.

The accomplishment of the technique of the operation is not difficult to one who is at all familiar with telescopic vision.

Thus, the first operation that was completed successfully from a technical standpoint with the new instrument was accomplished in twenty minutes. The ensuing operations have all been carried out in less than half an hour.

The instrument is readily introduced into the bladder owing to the coude-like beak, and, once introduced,

² This modification was developed by Dr. Caulk with the aid of Dr. Cackley, one of his postgraduates and with the assistance of Mr. Kenneth Drucker of the Philip-Drucker Instrument Company, in St. Louis who carried out the engineering problems of the instrument.

visualization is at all times present. The use of a fenestrator allows tissue to be brought into a position in which it remains until it is cut. The so-called punch grip, which has been many times described must be firm in order to squeeze the tissue tightly within the slot of the instrument. In this way one has a definite sense of security that the tissue will be accurately removed and that the instrument will not wobble in its position, as is frequently the case in instruments without a beak.

SUMMARY

In summing up the benefits offered by the instrument we wish to emphasize the following:

1 The instrument uses a cautery current, which has been proved to be the safest and offers the least mortality of all procedures in successfully attacking the obstructing prostate.

2 There is more complete visualization of the field and of the piece of tissue to be removed during the thrust of the blade than with any of the other instruments we have employed.

3 The technic of the operation is simple and will allow perfection to be obtained with a minimum sacrifice of life.

607 North Grand Boulevard

THE RELIEF OF PROSTATIC OBSTRUCTION

CLYDE W. COLLINGS, M.D.
NEW YORK

Prostatic obstruction is relieved in one of two ways through the cysto-urethroscope or through a suprapubic or perineal incision. It is of vital importance to the patient that the bladder neck obstruction be removed—if not, the resultant renal insufficiency will probably remove the patient.

Prostatectomy is too well known to most surgeons for me to comment on any particular feature of the operation. However, it is my present belief that a patient suffering from benign enlargement will be better off with a prostatectomy than with transurethral surgery in the hands of many urologic surgeons (especially those who perform only the odd transurethral operation).

Prostatic bars, obstructing prostatic carcinoma and scars, slight and moderate intra-urethral lateral and median lobes are ideally suited for urethroscopic excision by the trained transurethral surgeon. The markedly enlarged prostate, bulging into the rectum and urethra, had best be removed by prostatectomy.¹

A report of observations during the past ten years in relieving ward and private patients of obstructions of the neck of the bladder is presented.

SYMPTOMS

A patient with obstruction at the vesical outlet usually complains of frequent and painful urination. One sometimes sees a patient carrying a large residual urine with very little discomfort, and then again a patient with a small fibrous obstruction may have little or no residuum and marked frequency. Every urologist has seen patients with only slight urinary symptoms

suddenly develop an attack of acute complete retention. However, the usual story is one of slowly developing frequency of urination, in a few months infection occurs, and burning and urgency supervene.

In the group of private patients the chief complaints were frequency 33 per cent, burning 21 per cent, urgency 19 per cent, difficulty 17 per cent, acute complete retention 6 per cent, dribbling 2 per cent, chills and fever 1 per cent and urine through a suprapubic opening 1 per cent.

The duration of symptoms was recorded as six months or less, 21 per cent, from one to three years, 37 per cent, from four to ten years, 30 per cent, and from eleven to forty-two years, 12 per cent.

The age incidence varied from 5 to 92 years, in the first three decades, 12 per cent of the patients, in the fourth, fifth and sixth decades, 74 per cent, after these periods, 14 per cent.

Fig 1—Condition present on examination June 7 1933 J. I. R. a man aged 70 underwent a transurethral excision of a prostatic bar in April, 1923.

DIAGNOSIS

The diagnosis of prostatic obstruction was made by rectal examination, usually cystoscopy, but sometimes with the cystogram and urethrogram. The residuum varied from 0 to 870 cc. eleven patients had complete retention, and in four urine escaped through a suprapubic wound.

OPERATION

Forty-seven per cent of the patients had a bar operation, 21 per cent, bar and slight intra-urethral lateral lobes and carcinoma, 20 per cent, moderate intra-urethral and median lobes, and 5 per cent, scar following prostatectomy.

On the majority of patients I prefer to perform an electrical excision of the prostatic obstruction with the knife electrode (as described in 1925). One can predict the postoperative course and know that the complications will be unimportant, the patient will be up and about in a few days.

It is not easy to tell what is going to happen after an extensive resection with a loop electrode. Urologists

From the Departments of Urology, Bellevue Hospital and New York University Medical School.

Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

¹ Collings, C. W. J. Urol. 28: 529 (Nov.) 1932.

have all seen marked urethral chill with a temperature of 105 and 106 F, kidney infection, severe hemorrhage, incontinence, injury to the bladder neck by the 28 F bakelite sheath—at times uremia, septicemia and death. In my hands the marked intra-urethral and median lobe enlargement so encroaches on the lumen of the urethra as to make transurethral surgery extremely difficult. One cannot help causing traumatic bleeding which interferes with clear vision. After a prolonged operation, the patient sometimes develops a septic temperature. One then has the feeling that more adequate drainage could be obtained by a suprapubic tube. Mr. John A. Andrews of London stressed this point in discussing my paper on this subject before the Royal Society of Medicine in 1931.

Transurethral surgery is bound to be regarded unfavorably if indiscriminate attempts are made to remove every type of prostatic obstruction. The beginner should certainly observe a qualified trans-

neck. One excises from 3 to 9 o'clock until a distinct concavity is seen (all visible obstruction removed).

COMPLICATIONS

Eleven per cent of transurethral patients had severe urethral chills and fever. All these patients had had the loop and knife excision of the obstructing portion of the prostate. It was rare that a knife excision patient had over a degree or two of fever.

Sixty per cent of the private patients had no bleeding following operation, in 32 per cent the urine was pink for one or two days, in 7 per cent the urine was pink with small clots for three or four days. One patient had secondary bleeding fourteen days after operation, another clots off and on for nine days, both controlled by an indwelling catheter. One patient continued to bleed so much following operation that I had to do an immediate suprapubic cystotomy. A tear was found in the bladder neck (thought to have been caused by forcibly passing the 28 F sheath through the tight bladder neck). In a Bellevue patient incontinence developed after operation. Because of a weak rotary converter I was using a coagulating instead of a cutting current. Twelve days after operation the patient had a secondary hemorrhage and the posterior layer of the triangular ligament sloughed away.

FREQUENCY AFTER OPERATION

Patients with nocturia of from one to eight times before operation gave the following reports after operation. Sixty-one did not get up at all at night, 23 per cent got up sometimes once, and 16 per cent got up once or twice. Judging the results from a broader angle 84 per cent were relieved of burning urgency and frequency, 10 per cent were partially relieved, 4 per cent the symptoms were the same, and in 2 per cent of the patients could not be followed.

RESIDUUM

The residuum after operation was recorded as follows. Ninety per cent of the patients empty the bladder completely, 9 per cent carry from 7 to 45 cc, and in 1 per cent the amount was undetermined. The time since operation was, in 62 per cent, from one to five years and in 38 per cent from five to ten years.

CYSTO-URETHROSCOPIC EXAMINATION

In the majority of these patients, urethroscopy was done after operation. Eighty-eight per cent showed a wide open valley in the posterior urethra, the obstruction all removed, and a normal appearing mucous membrane with little or no scarring, the intra-urethral lobe cases showed a concavity when there had been a convexity before, 7 per cent developed small intra-urethral lobes a year or so after a bar operation or recurrent carcinomatous obstruction of the bladder neck and required a second operation, 5 per cent developed small intra-urethral lobes from one to five years after a bar operation but are free from symptoms or residuum.

The following are some of the reasons for doing transurethral surgery instead of prostatectomy. Twenty-two patients were physicians or the father of a physician, and transurethral surgery was requested, twenty-three patients refused to have a prostatectomy (often because of some friend's experience), fourteen patients had a medical complication, such as a cardiac condition, renal insufficiency or advanced age, precluding prostatectomy, for eleven patients the referring physician requested transurethral surgery (if at all possible), two

Fig. 2—Condition present on examination June 7, 1933. U. C. a man aged 68 underwent a transurethral excision of moderate enlargement of intra-urethral lateral and median lobes in February, 1932.

urethral operator several times before attempting the operation himself. Furthermore, he should work on minor obstructions until thoroughly familiar with all landmarks, carefully perfecting his technique. I have had three patients develop traumatic strictures at the bulbomembranous junction following the use of a 28 F bakelite sheath. I use a 24 F cysto-urethroscope with the knife electrode and 26 F bakelite sheath with the knife and loop electrodes.

The floor of the bladder neck is excised from 5 to 7 o'clock in patients with fibrous obstruction. By turning the knife blade sideways, small intra-urethral lateral lobes are excised by pushing the electrode in and out (from the verumontanum and just through the bladder neck). With the newer types of spark gap machines, the operation may be performed with great care and precision in approximately ten or fifteen minutes.

For moderate intra-urethral lateral and median lobe obstruction, the knife and loop electrodes are used. The loop is moved by hand from the verumontanum down the posterior urethra and through the bladder

patients, aged 5 and 25 years with congenital bari, were best relieved by transurethral excision

DIATHESIS

Six patients died of cardiac failure, an average of one year and two months after operation, the ages being 70 71, 74 75 77 and 92

Three died of pneumonia

J G aged 80, with extensive carcinoma of the prostate, died two weeks after operation

W V aged 70, with metastasis from carcinoma of the prostate died one month after operation

P G aged 73 with moderate enlargement of intra-urethral and median lobes died one month after operation. As further complications he developed gangrene of the lung and bilateral pyelitis

F B, aged 70 with extensive carcinoma of the prostate with metastasis to the bones and abdominal cavity, died three days after operation of paralytic ileus

Dr J L L, aged 62 committed suicide two and one-half years after operation

I have not included in this series the operative results on patients admitted to New York University. This rather large group was made up of fibrous and small and moderate benign enlargement of the prostate. Patients with marked enlargement are sent to Bellevue Hospital (usually for a prostatectomy). Because of the difficulty in following these patients over a period of years, a complete report is not available. There were no operative deaths or serious postoperative complications. Two patients had secondary hemorrhage. The clots were removed by means of a Bigelow evacuator, after which an indwelling catheter stopped any further bleeding.

In Bellevue Hospital from January, 1928 to June, 1933, we performed 260 prostatectomies (in the main a two-stage suprapubic operation). Following prostatectomy, twenty-two, or 8.5 per cent, of the patients died. These figures do not represent the prostatic surgery record (such a record would include the patients who died following vasectomy or suprapubic cystotomy only). There were thirty-three patients operated on by loop resection, of these, two died. Twenty-eight had electrical excision with the knife electrode, with no deaths. The percentage of deaths following both types of transurethral surgery was 3.2 per cent as compared to 8.5 per cent following prostatectomy.

Throughout this country the pendulum of transurethral surgery has swung high and low. As I stated before this section in Portland in 1929, time alone will accord this method its proper place in relieving prostatic obstruction.

SUMMARY

1 It is important to remove prostatic obstruction, or the obstruction will probably remove the patient

2 If the patient would heed the first danger signals of frequency, burning and difficulty, many lives could be saved

3 Slight and moderate prostatic obstruction can be efficiently excised through a cysto-urethroscope. Marked enlargement can best be relieved by prostatectomy

4 Transurethral surgery requires special skill even in the hands of a trained cystoscopist

5 Bleeding has been unimportant with the latest type of spark gap machine

6 After operation, the cysto-urethroscope shows a deep, concave valley in the prostatic urethra. The relief may be permanent, as some of these patients are in their eleventh year

983 Park Avenue

ABSTRACT OF DISCUSSION

ON PAIRS OF DRS. CALIK AND LATTON AND DR. COLLINGS

DR. F. E. B. FOLLY, St. Paul. The further appraisal and rationalization of this fascinating new departure is quite obviously the main event in urology today. It is said repeatedly that the limitations, dangers and shortcomings of resection are kept concealed. That may have been true at the start, but at the present moment the contrary is true. Not only must the patient be individualized as pointed out by Dr. Engel and Dr. Lower, but the surgeon in his relation to these new methods also must be individualized. An appraisal of resection adequate for one surgeon may be entirely erroneous for another. Urologists have gone far enough to recognize this fact definitely and should abandon further attempts at blanket conclusions as they are useless. What instrument to use, what generator to use is entirely a question for the individual surgeon, beyond these there is no question.

DR. T. J. KIRWAN, New York. The projection of heat into remote portions of the prostatic tissue when the high frequency cutting current is being used hardly seems possible to me. Cell change takes place only after a 20 degree rise in temperature which could scarcely be generated at so remote a point with the currents ordinarily used. No material conducts heat instantaneously, it requires time to flow and its passage is accompanied by rapid decrease in effect. I am in accord with the views of Dr. Collings concerning the promiscuous employment of intra-urethral methods by those who have not had much experience. The method he first described wherein he cuts a wedge between 7 and 5 on the clock dial and then whittles away the intervening tissues, would seem to me certain to leave coagulated tissue which will later slough and cause trouble. Coagulating just what is caught in the fenestra and then cutting this away with a sharp knife seems to me preferable. The clean wound heals readily. Tissue destroyed in situ is more likely to be infected and delay recovery. Tremendous stress has been laid on the design and type of instrument with which vesical neck resection is to be accomplished. These are of little importance. Diagnosis is most vital, together with the ability to remove the obstruction with little damage. Urologists should standardize the management of the electrical element in vesical neck resection. A committee might be appointed by the American Urological Association—including electrical engineers if possible—to pass on the different types of current used in the work and to establish scientifically just what each is able to accomplish. Just this is now being done with the shrinkage method. Because of the exactness with which radiofrequency currents may be controlled with the vacuum tube generators at present available, the amount of heat can be regulated in a way never before possible. This makes available current densities ranging between the mild effects used in diathermy, to the high densities needed for cutting. It has been established that tissue cells succumb to the lethal effects of heat before those of blood or lymph are seriously injured. Therefore it is reasonable to assume that the products of tissue cell death may still be carried off by the circulation of the area thermatized. This ought to prevent necrosis and its untoward reaction. These ideas are in their infancy, but the prospect of instituting a nondestructive procedure for the relief of many forms of obstruction in the urinary tract seems good.

DR. C. H. DE T. SHIVERS, Atlantic City, N. J. I agree with Dr. Collings that the operation is one that requires special training and aptitude in the use of urethral instruments. The current used in this work is a matter of individual choice. I

have used the spark gap machine and have been well satisfied with the results. I have not attempted in the clinic to resect any very large intravesical intrusions either lateral or median, with but one exception, and that was a failure because of the accompanying hemorrhage. This patient later had a two stage prostatectomy with an uneventful recovery. I feel not only that the large prostate is difficult to resect but also that the accompanying danger of hemorrhage and infection is much greater. I do not advise a repetition of the resection unless sufficient time has elapsed between operations. I have been particularly interested in the length of time it takes before urethral convalescence has been completed. I have seen ulceration of the prostatic urethra three months after the operation in cases in which resection was done elsewhere and in my clinic I have noted a delay in convalescence in certain cases. I feel that it is extremely important to control the bleeding as one proceeds with the operation. I do it entirely with ball and loop electrodes. If properly done this does not coagulate tissue to any degree beyond the point of bleeding. In my service at the Atlantic City Hospital we have been using the high tension spark gap machine of Collings and the hal elite sheath lens and loop electrode of McCarthy now for a year and a half and have made eighty-two resections thus far without a death. All of these with the exception of three had excellent functional results. One had an incomplete resection because of a hemorrhage. The other two patients have a moderate sized vesical diverticulum but owing to their advanced age and poor physical condition it was deemed inadvisable to do a diverticulectomy. I should like to speak about the preparation of patients for resection. I feel that they deserve the same care as patients who are to undergo prostatectomy. This is too serious a procedure to make it an office operation.

DR ABRAHAM RAVICH, Brooklyn. I am in accord with the remarks of Drs. Caulk and Patton about the Caulk method of prostatic resection. In 1926 I had presented what I believe was the first cautery punch with visualization under water at the meeting of the American Urological Association in Baltimore, and reported about thirty cases in which resection was done with this instrument. With the cautery punch method I do not recall the extremely troublesome bleeding, the ascending kidney infections, the persistent pyuria and invalidism that so frequently follow the present methods of prostatic resection by high frequency current. With improvement in the instrumentation such as Drs. Caulk and Patton have presented it seems to me that the results will be superior to those obtained by many of the high frequency currents now in use.

DR JOHN R. CAULK, St. Louis. I am glad to hear Dr. Ravich say that he noticed less trouble when he was using my cautery punch than with the high frequency resection. Both experimental and clinical evidence bear this out. It has been definitely determined that there are produced in the tissue varying degrees of heat, more pronounced near the active electrode, as a result of the waves concentrating at the active electrode. This one must realize. It is actual. On the supposition that there should occur only a 3 mm. destruction of tissue it is easy to see that, if one should be operating in the outer confines of the prostate the slough produced could easily cause extravasation. We have found that the waves of current select the blood stream and if temperatures are taken at different places in the body it will be found that the highest temperatures are recorded along the large vessels. One of the first effects of even a short current application is the cutting down of the blood flow in tissue which is responsible for late reactions. The currents seem to act specifically on the vascular system.

DR C. W. COLLINGS, New York. Dr. Foley has brought out the important point of the size of obstruction—small and moderate enlargement may be relieved transurethrally, large obstruction by prostatectomy. As Dr. Kirwin has stated one should use the transurethral operation one is familiar with—the method that works best in one's hands. Dr. Shivers has mentioned the unfortunate commercialism practiced by some of the manufacturers of electrical machines. I urge as I did several years ago that the operator try out several types of these machines and choose the one that best suits his needs.

Clinical Notes, Suggestions and New Instruments

A DEVICE FOR TRANSPORTING PATIENTS WITH REDUCED FRACTURE OF FEMUR

CARL J. HOLLINGWORTH, M.D., PORTLAND, ORE.

Occasionally it is necessary to move, sometimes for a considerable distance, a patient with a fractured femur which has not yet united but which has been reduced by traction. The problem then arises of how to make such a change with the least pain and distress to the patient and, if possible, without loss of the extension that has already been gained. Of course, a Thomas splint can always be used if one is available but for the benefit of those who may not have such an apparatus at hand I want to suggest a very simple device, which was used recently with great success.

It was desired to move a child, aged 2 years, to her home across the city. She had been in the hospital three days during which time overriding of the fragments had been eliminated by weights and vertical overhead extension of the injured leg. The father of the child devised a frame such as is shown in the accompanying illustration, which very satisfactorily solved the problem. The details of construction are quite clearly shown so that further explanation along this line is unnecessary.

Device for transporting a patient with a reduced fracture of the femur

The patient was placed on the frame, to which she was securely fastened, as shown, while the weights were still attached to the extended leg. Steady traction was maintained while the weights were detached and the cord was reattached to the coil spring. The patient on the frame was placed on the back seat of the automobile where she rode undisturbed, even by the jolting when crossing street car tracks, and thus, what we had anticipated as a very painful journey was made with complete comfort.

An overhead frame had been prepared for the home care of my patient. The transporting frame was placed on the bed and the cords, pulleys and weights were attached to the injured leg before removal of the frame. In this manner there was the minimal loss of extension as well as a minimum of discomfort to the patient.

While this frame was devised for moving a small child, it could easily be made to accommodate any child in whose case vertical extension is being used. For any patient under treatment with Buck's extension, the same principle can readily be utilized merely by changing the upright portion of the frame so that it is more nearly parallel with the body. Any degree of elevation that is desired can thus be secured and, by varying the size and strength of the coil spring, full extension could be maintained.

UNUSUAL REACTION SIMULATING ALLERGIC SHOCK

C I WALDROTT MD AND M S ASCHER MD DETROIT

Reactions following injections of antigens manifest a great variety of symptoms. In addition to the urticahc type of reactions, during the course of which the known symptom of allergy may arise there are many reactions that have no association with allergy, for instance, reactions due to fever-producing substances, to certain drugs syncope and the like may appear following therapeutic injections. Thus the clinical appearance may become greatly confused. An unusual reaction presenting a rather serious aspect and found to be entirely on a neurotic basis without any relationship to the antigen injected is here-with reported.

M K, an obese woman, aged 40, had been treated successfully for fall fever with extracts of grass and short ragweed for the past three years without having experienced other than local reactions. In July, 1933 after she had received several small doses of pollen extract without disturbances she suddenly began to have a paroxysm of coughing dyspnea and yawning following an injection. This condition was promptly alleviated by the use of a tourniquet and the injection of a few minims of epinephrine. With each successive treatment the symptoms became more aggravated even though the doses were decreased. While at first there was a time interval of from ten to twenty minutes between the time of the injection and the appearance of the symptoms this interval gradually lessened so that a severe attack of coughing, dyspnea and yawning followed almost immediately after the injection. The pulmonary manifestations resembled closely those of a severe attack of bronchial asthma. There were many rhonchi and a marked emphysema throughout the chest. Urticaria was not noted. The symptoms became so severe that it was decided to discontinue with further treatment.

The occurrence of yawning and, particularly, the absence of urticaria and the short interval of reaction aroused our suspicion. Physiologic solution of sodium chloride was substituted for the pollen extract without the knowledge of the patient. The symptoms occurred with the usual severity. After the patient was informed of the deception, the symptoms perceptibly abated and subsequent treatments could be carried out without any further disturbances.

Since the patient had not previously given us reason to suspect that she was neurotic, and since this is the only case encountered in a large series in which therapeutic injections were given, this report is deemed to be of sufficient value to warrant publication. Moreover, it offers an excellent demonstration of the fact that attacks of 'asthma nervosum' may be practically identical with those of true allergic asthma.

CONTACT ECZEMA DUE TO CLOTHING

FRANK A SIMON MD AND FRANCIS M RACKEMANN MD
Research Fellow in Medicine and Physician Respectively Massachusetts
General Hospital

BOSTON

Ecze-ma due to contact with various substances in the environment is a well recognized condition to which the literature contains many references.¹ The diagnosis of the cause in the individual patient is not easy, and the case reported here demonstrates the need of prolonged study and observation and the good results that will reward the effort. It also shows how widely distributed the cause of trouble may be.

REPORT OF CASE

A man aged 29 developed a small area of ecze-ma on the left wrist in November 1928. Similar lesions soon appeared on the dorsal aspect of both hands and fingers. They were of the acute vesicular type, with oozing and thickening of the skin. It is of interest to note that the lesions made their first appearance at the site of an abrasion caused by a stiffly starched

cuff. Various local applications had no apparent effect on the course of the disease. Roentgen therapy in the spring and again in the fall of 1929 resulted in temporary improvement.

In April, 1930, an acute exacerbation of typical vesicular 'dermatitis venenarum' of the hands, forearms, neck and ears confined the patient to the hospital for two weeks. Improvement was rapid, and at the time of discharge the skin was almost normal in appearance. Immediately after the patient left the hospital, the lesions recurred on the hands and persisted until June, 1930, when in the course of a month's vacation they disappeared entirely. During this vacation he was camping out and did not wear his 'city' clothing. In July, when he returned to work the lesions recurred on the hands as before, and similar lesions appeared on the feet and ankles.

In the meantime, repeated microscopic examinations and cultures failed to reveal fungi. A general physical examination gave no evidence of focal infection. The possibility of sensitization was considered at this time. Skin tests by the scratch method with extracts of all foods in the patient's diet and with many epidermal products and pollens all gave negative results.

The lesions on the ankles did not extend above the top of the socks and disappeared when white socks were substituted for those previously worn. These facts suggested clothing as a cause of the lesions elsewhere, so a patch test was made by applying a piece of fabric from a blue serge suit to the skin and holding it in place with adhesive tape. In twenty-four hours a typical patch of ecze-ma was produced with redness, swelling, and vesicles which corresponded exactly in size and shape with the patch. Patch tests were made with other articles of clothing and positive results were obtained from a brown suit, a dark blue overcoat, black hse socks, and a piece of black rayon. All gave negative tests on a control subject.

From the fall of 1930 to the spring of 1933, ecze-ma continued intermittently, and every time the cause of the recurrence was identified by a study of the location of the lesions, by the history of activities and of contacts, and finally by patch tests. Proof was obtained in every instance by a disappearance of the lesions when the contact was avoided.

The following were the most important and most interesting of these recurrences: lesions on the neck from the collar of the overcoat, on the forehead from the hat band, on the legs from garters, on the feet and ankles from socks and shoes, on the feet, legs, hands, arms, face and neck from bed clothing, on the hands from automobile upholstery, on the hands and forearms from the varnish on a mahogany table, the linings of two suits, his wife's dresses, and the upholstery of living room furniture. Lesions on the face, eyelids and genitals were shown to result from transference of the allergen by the fingers. On one occasion the eyelids were so swollen that the eyes could not be opened.

Since the spring of 1933 (four months) the patient has been free from ecze-ma with the exception of a few very mild and very brief recurrences, which were checked immediately by discovering the source of contact and avoiding it. By exercising great care in avoiding certain contacts, he is now able to follow his regular occupation and lead a normal life. However, he has learned that every dyed fabric in clothing or furniture must be tested by the patch method before it can be purchased and used by him.

Further study of the patient was interesting. In order to determine which constituent of the fabric was responsible for the hypersensitiveness, patch tests were made with several 'pure' substances: (1) clean wool (2) clean unbleached cotton, (3) undyed silk (4) four mordants used in dyeing, (5) a bleaching agent and (6) six commercial dyes. All solutions were tested by moistening a piece of gauze with them and applying it to the skin with adhesive tape. All the pure substances gave negative tests except three of the dyes, which produced typical areas of ecze-ma. When however these substances were tested by the scratch method, no reaction occurred. All tests on a control subject were negative. In order to show that the reaction depends on the dye and not on a combination of the dye with protein or some other constituent of the fabric asbestos instead of gauze was used for some of the tests, and with similar positive results.

Later on patch tests with twenty-six different 'pure' dyes were made. Eleven of them gave positive results on the patient.

Huber H L and Harsh C F A Summer Dermatitis Caused by a Common Weed J Allergy 3 5:8 (Sept.) 1932.

and negative results on the controls. All of these were repeated at least once with the same result. All the 170 dyes tested gave positive tests, some strong, others weak. Other types of dyes were all negative with the exception of three triphenylmethane dyes, which were weakly positive.

An attempt was made to determine what part of the dye molecule carries the specific properties by making patch tests with comparatively simple chemically pure compounds related to the dyes in chemical composition. Twenty-six substances varying in complexity from aniline and trimethophenol to alpha-naphthylamine and resorcinol were applied as patch tests but all gave negative results. The simplest compound that gave a positive test was dimethylnitrobenzene which was strongly positive on the patient and negative on each of ten controls.

A study of the influence of side chains and of the physical properties of the compounds would be interesting, but would require the use of a number of rather uncommon chemically pure compounds, which were not available. The triphenylmethane compounds have not been investigated.

Local passive transfer (Pruisnitz-Kustner reaction) was studied, the strongly reacting 170 dyes being used to test the site in the normal recipient treated by the patient's serum but the result was entirely negative as was to be expected from the results of similar studies in other laboratories.

SUMMARY

1. A man, aged 29 long suffering from localized areas of eczema, was found to be sensitive to the dyes in a wide variety of fabrics.

2. The patch test was of the utmost importance in diagnosis and continues to be of great importance in treatment as a means of preventing contact with new clothing and other materials likely to cause trouble.

3. Study showed that a variety of dyes and not a single dye was responsible for the symptoms.

Massachusetts General Hospital

TUBERCULOSIS OF THE BREAST

CALF L. WILSON, M.D. SEATTLE

Primary tuberculosis of the breast is still a relatively uncommon pathologic lesion, in spite of the fact that it was first described by Sir Astley Cooper in 1829 in a paper entitled 'Scrofulous Swellings of the Breast'. A short time later Velpeau mentioned tuberculosis as occurring in the mammary gland, only to be flatly contradicted by Virchow who wrote in his famous 'Treatise on Tumors' that tuberculosis never occurred in the breast. At the close of the nineteenth century, Durbar first demonstrated the tubercle bacillus in breast tissue. In 1902 Binda de Vecchi was able to find seventy-seven cases reported in the literature and added one of his own. Four years later, Briandle reported eleven additional cases from the Tübingen clinic. In 1913, Powers of Denver reported four cases, bringing the total reported to ninety-three. De Costa in the ninth edition of 'Modern Surgery,' stated that of the hundred cases reported, only eighty were actually histologically or bacteriologically confirmed.

REPORT OF CASE

Mrs. A. C., aged 62, an Italian widow, first seen at home Sept. 26, 1932, complained of swelling of the left breast and arm, swelling of the feet and ankles, weakness, and shortness of breath. The family history was negative for familial disease.

The past history was negative for any serious illness. The patient was the mother of eight children, all normal pregnancies. Five children, all of adult age, are still living. There had been no miscarriages or stillbirths.

The present illness began about two years before with a lump appearing in the lower outer quadrant of the left breast. The lump enlarged and other lumps appeared in the upper outer quadrant of the same breast. There was no pain. The breast gradually enlarged during the following year until it was half again its normal size. About eighteen months after the first lump appeared the left axilla began to enlarge and for the first time pain occurred in the arm, beginning in the axilla and extending down the inner side of the arm and forearm. At this time the patient consulted a physician, who

removed one of the axillary glands and performed a Wassermann test. He told the patient that she had syphilis and gave her a course of sixteen treatments with arsphenamine, with no improvement in her condition.

About one week before she called me she became very weak and had difficulty in breathing, her left arm and both feet and ankles began to swell, and she could not get out of bed.

At the examination September 26, she was slightly icteric and was breathing heavily and rapidly. The lips were slightly cyanotic. There was a walnut sized nodule in the left supraclavicular fossa. The left breast was twice the size of the right, with 'pig skin' puckering over the entire lateral half of the breast but there was no retraction of the nipple. The entire breast was firm and filled with matted nodules all seemingly attached to the region of the nipple. The organ was still movable, but not as freely as the right breast. There was a chain of small firm almost stony nodules extending up along the lateral edge of the pectoralis major muscle, ending in three walnut sized masses in the left axilla. There was also a 3 inch biopsy scar in the axilla.

The heart was normal in size with a systolic murmur at the apex and systolic and diastolic murmurs at the base, with a rate of 135. The lungs showed moist rales at both bases but no demonstrable dullness. The liver was soft, smooth, doughy and tender and extended three fingerbreadths below the costal margin.

The left arm, forearm and hand show marked pitting edema, with tenderness along the course of the median and ulnar nerves in the arm. The feet and ankles showed marked pitting edema almost up to the knee.

The blood pressure was 150 systolic 65 diastolic the pulse, 135 the temperature 98.6 F. Analysis of the urine showed a specific gravity of 1.010 and a faint trace of albumin and no sugar, acetone or diacetic acid. There was no sediment.

The diagnosis at this time was bronchopneumonia, cardiac decompensation and carcinoma of the left breast, with metastases. The prognosis at this time was extremely poor.

The patient was immediately given supportive treatment including digitalis and responded very promptly, so that by October 7 the pulse was down to 80 and the temperature, which had risen to as high as 102 F. down to 98.6 once more. The lungs were free from rales breathing was more easy and the feet and ankles were almost back to normal size. The swelling of the breast and arm was constant however, and she still complained of great pain from the axilla to the elbow.

During the following two weeks there was no gain in strength and the axillary and supraclavicular masses increased in size so on October 21 the patient was sent to the Columbus Hospital to be made comfortable until her death. At this time the breast was about the same size as when first seen a month before but the axillary mass was now the size of an orange and the supraclavicular mass was the size of an egg. The posterior cervical lymph nodes had enlarged and at first discrete, became confluent and enlarged to form a mass almost the size of a hen's egg.

On admission the laboratory reported the hemoglobin 45 per cent and the red cells only 2,810,000 with 15,300 white blood cells, 78 per cent being polymorphonuclears. The urine and repeated blood Wassermann reactions were negative.

During the remainder of the month of October the heart and lungs remained normal, the liver gradually became reduced in size but remained tender, and the edema of the left arm and hand became somewhat reduced. The spleen, however, began to enlarge, so that from a normal size in September it reached the iliac crest by the end of October. Three Wassermann tests on the blood were negative. The breast became larger and more painful, and the line of infiltration of the pectoralis major muscle became so great that the entire muscle stood out prominently as though it belonged to the strong man of a circus.

On a high vitamin high caloric diet the patient seemed to improve slowly, so on November 19 transfusion was done, and the following week she was taken to the surgical department where the supraclavicular mass of glands was removed for diagnosis. At operation the glands were found to be matted together and adherent to the fascia, external jugular vein and spinal accessory nerve, from all of which they were removed.

by sharp dissection. The wound was closed without drainage and healed uneventfully.

The tissue that was removed grossly appeared to be metastatic carcinoma, but microscopically it showed a rather typical proliferative type of tuberculous lymphadenitis, with many young fibroblasts and many giant cells. There was no degeneration and no evidence of malignancy or of gumma.

When the patient came into the hospital she brought with her a bottle of a patent preparation of cod liver oil that contained among other things, 17 per cent of alcohol. She took her diet well, ridged and abetted by this alcoholic oil preparation and left the hospital December 8. When she left the hospital she was able to sit up out of bed most of the day, to walk to the lavatory alone and to wash herself without help.

In August, 1933, eight months after the patient left the hospital she was progressing nicely. She had kept on a high vitamin diet and her cod liver oil and had taken sun baths, and two months before she decided to take a boat trip to California, where she could get more sunshine and possibly some beverage with less cod liver oil in it.

COMMENT

Aside from the relative rareness of tuberculosis of the breast with no demonstrable focus of tuberculosis anywhere else, this case is interesting because it was first diagnosed as syphilis and treated as such, clinically it was definitely carcinoma, and histologically the metastatic glands showed it to be definitely tuberculosis. It is the first case of primary tuberculosis of the breast to be seen in more than 31,000 cases at the Polyclinic in Seattle.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

ULTRAVIOLET THERAPY IN ORAL DISEASES

The Council on Dental Therapeutics of the American Dental Association has adopted a report concerning the therapeutic use of ultraviolet radiation for the treatment of oral diseases and conditions. This report, the Council on Physical Therapy believes, will be of as much interest to the general practitioner as to the dentist.

While investigating ultraviolet radiation apparatus and reviewing propagandizing literature for the appliances, the Council on Physical Therapy noted in some instances that, along with clinical indications and therapeutic claims intended primarily for the attention of the physician, odontologic claims were recorded side by side. In other instances separate booklets were prepared for the attention of the dentist. In general, the following indications, conditions and diseases were found in the advertising matter: abscesses, alveolectomy (analgesic effects), antrum, bacteria, bactericidal action, biological effects, bone regeneration, calcium deposition, calcium fixation, degrees of reaction, dental caries, dry socket, extractions, fistulas, fractures, germicidal action, gingivitis, granulations, hyperemia, infection, neuralgia, neuralgia atypical, osteomyelitis, oxidizing pain after extraction, periapical infections, periodontoclasia, post-operative pain, prosthodontia, pyorrhea, rarefied area, rarefied bone regeneration tissue, sinus surgery stimulates stomatitis, tic douloureux, trismus, Vincent's angina, Vincent's infection, acute and Vincent's infection.

Before the Council on Physical Therapy could accept apparatus for which these claims were advanced, efforts were made to secure the proper evidence. Hence, manufacturers of the apparatus were asked to submit adequate evidence to substantiate the odontologic claims but to date the Council has received nothing that would warrant it in accepting ultraviolet radiation apparatus recommended for use in the treatment of oral diseases and conditions. Therefore the Council on Physical Therapy asked the Council on Dental Therapeutics to cooperate in the investigation.

Essentially, the Council on Dental Therapeutics reported that many of the claims made were greatly exaggerated and that the evidence given in the promotional literature or in references to dental literature does not justify the dental profession in adopting ultraviolet radiation as a useful therapeutic agency.

Before abstracting this report, the Council on Physical Therapy takes this opportunity to express to the Council on Dental Therapeutics of the American Dental Association its hearty appreciation of the cooperation it has rendered in connection with this problem.

Under the caption "Validity of the Evidence," the report of the Council on Dental Therapeutics states:

The physical characteristics of the light emitted by these various machines is not in dispute. From the foregoing it may be admitted that on a physical basis, all of these will agree with the claims advanced. The point at issue is how valid are the claims and suggested indications for the use of these instruments in the treatment of dental conditions?

Considering the subject as a whole, the report states:

The fact that local application of ultraviolet light has been used by some dentists for almost ten years with no more convincing evidence than that presented by its promoters and enthusiasts leads one to reiterate until more carefully controlled evidence is at hand it is not wise to recommend the machines to the dental profession.

In some cases, reprints of articles that appeared in dental journals regarding the use of ultraviolet radiation in dental surgery were utilized as merchandising literature. Discussing the extract from one of the reprints, the Council on Dental Therapeutics writes:

The extract is more in the nature of a high class testimonial. Indeed much of it has the appearance of being taken directly from promotional material of the firm. It is claimed that ultraviolet has bactericidal action, induces hyperemia and an accelerated deposition of calcium.

Reading further into the report:

This discussion is concerned only with the momentary local application of ultraviolet light by means of special dental applications. It may be admitted that ultraviolet light has some bactericidal properties *in vitro* but no adequate evidence or references to adequate evidence appear in the promotional material of the firm, to show the germicidal effects and what may be expected of them when used *in vivo*. No amount of seriousness can be attached to the claim that the deposition of calcium is accelerated when ultraviolet rays are applied locally. This is a definite statement which should be supported by adequate data—chemical, histological or otherwise and with suitable controls. It would be too far afield from the present purpose to discuss in detail calcium metabolism for this involves not only a discussion of the accessory factors such as irradiated ergosterol, vitamin D and light in the ultraviolet region but also involves a discussion of the calcium-phosphorus relation of the blood and tissues. Nor is there any valid evidence known to the referee that the Calcium and Phosphorus relations of the blood are greatly altered by local applications of ultraviolet light which would shorten the term of union of fractures. One cannot escape the impression that careful rest nursing etc. is of first importance. None of this fundamental information appears in the advertising.

In another portion of the report the advertising under discussion concerns the virtues of the use of ultraviolet radiation in connection with postoperative pain following the extraction of teeth or other surgical procedures, whether due to dry socket, infective osteitis or traumatism, during local anesthesia. The extract from the advertising matter recorded all these conditions as being readily suppressed with ultraviolet therapy. In the consideration of this point, the Council on Dental Therapeutics writes:

The response of individual patients following the extraction of teeth or any other surgical procedure whether due to dry socket, infective osteitis or traumatism during local anesthesia is variable and depends on a number of factors. Hence it would require a great deal of detailed descriptive and statistical evidence to permit one to reach a valid conclusion. As the statement stands it is nothing more than a testimonial.

How much of the supposed beneficial effect was due to heat and how much was due to light of short wavelength is difficult to tell from this account. Patients suffering from trifacial neuralgia are known to have periods of remission. Conservative neurological opinion holds that the only available method for alleviating trifacial neuralgia is by conservative or radical surgery. Since the claim is contrary to the well accepted findings of competent workers in the field it should be obvious that more evidence than is contained in these five lines is necessary. For example, what methods were used to fix the diagnosis, the condition of the patient, the natural periods of remission, the response to other forms of treatment, the comparative response to heat and short waves of light etc. etc.

In the concluding paragraph, the Council on Dental Therapeutics recommended that the Council on Physical Therapy be advised that no adequately controlled evidence had been presented in descriptive literature and advertising matter to warrant the use of ultraviolet radiation in the treatment of oral diseases and conditions.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEPCH, Secretary

NEO-IOPAX—Di sodium λ -methyl-3,5-diiodo-4-pyridone-2,6-dicarboxylate— λ -NaOOC(CO)NC(CH₃)(COONa). The disodium salt of λ -methyl-3,5-diiodo-4-pyridone-2,6-dicarboxylic acid. Neo-Iopax contains 51.5 per cent iodine.

Actions and Uses—Neo-Iopax is used as a contrast medium in intravenous urography. It has advantages over Iopax in that a smaller dose is required, the volume of solution injected is much less and the drug is excreted in the urine in relatively higher concentration. Clinical reports indicate that systemic reactions occur uncommonly and are usually mild and fleeting. In some cases there is more or less severe pain in the arm radiating to the shoulder, usually this disappears on completion of the injection but in a small percentage of cases it may persist for a variable period. The pain may usually be relieved by local applications of heat and the administration of an analgesic when necessary. If only anatomic information is desired it is usually sufficient to take a single roentgenogram from twenty to thirty minutes after injection. In other cases a series of roentgenograms are taken at intervals of ten thirty and fifty minutes after injection. Before the second picture is taken the bladder is emptied in order that the shadow of the drug in the bladder may not obscure the lower parts of the ureters. If the first plates show that but little of the drug has been excreted it is presumed that the kidneys are functioning poorly and several hours should be allowed to elapse during which plates should be made at intervals. Impairment of renal function will allow but poor concentration of the drug, many hours are then required for its excretion. The use of the drug is contraindicated in patients with severe liver disorders, nephritis, tuberculosis or hyperthyroidism and great care must be exercised in cases of uremia. Caution must also be exercised in patients with any severe systemic disease. Preliminary liver and kidney function tests are advisable in suspected cases.

Dosage—Twenty cc of a solution containing 15 Gm. of neo-Iopax previously warmed to body temperature is injected intravenously, very slowly into the cubital vein. Children are given correspondingly smaller doses.

Manufactured by Schering-Kahlbaum, A. G., Berlin, Germany (Schering Corporation, New York distributor). U. S. patent applied for. U. S. trademark, 297,925.

Ampoule Solution Neo-Iopax 20 cc. Each ampoule contains neo-Iopax 10 Gm. dissolved in sufficient sterile distilled water to make 20 cc.

Neo-Iopax occurs as a white crystalline odorless powder, very soluble in water, insoluble in acetone, benzene, chloroform, ether and purified petroleum benzene. An aqueous solution is neutral to litmus.

Dissolve about 0.5 Gm. of neo-Iopax in 100 cc. of water, add an excess of diluted hydrochloric acid, collect the liberated λ -methyl-3,5-diiodo-4-pyridoxyl-2,6-dicarboxylic acid on a filter, wash and dry in a desiccator over sulphuric acid under a partial vacuum; it melts at about 174°C. with decomposition, heat the remainder of the resultant acid at its decomposition temperature (about 175 to 180°C.) until no further evolution of gas is noted; the residual substance, λ -methyl-3,5-diiodo-4-pyridone, thrice recrystallized from water, melts at 214°C. to 1 cc. of the foregoing filtrate add 10 cc. of urinary zinc acetate solution, a yellow precipitate results. Dissolve about 0.5 Gm. of neo-Iopax in 50 cc. of water, add an excess of hydrochloric acid, filter through paper and divide into two portions; to one portion add 1 cc. of chloroform and 0.1 cc. of ferric chloride solution, no coloration is imparted to the chloroform layer (absence of free inorganic iodide); saturate the other portion with hydrogen sulphide, no coloration or precipitation results (salts of heavy metals).

Dry about 1 Gm. of neo-Iopax accurately weighed to constant weight at 100°C. the loss in weight does not exceed 2 per cent. Transfer about 1 Gm. of neo-Iopax accurately weighed to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, third edition, page 20, chapter 2, paragraph 22, the percentage of nitrogen corresponds to not less than 2.7 per cent nor more than 2.9 per cent when calculated to the dried substance. Weigh accurately about 0.5 Gm. of neo-Iopax in a tared platinum dish, add 10 cc. of sulphuric acid, gently heat while fumes of iodine and sulphur trioxide are evolved, repeat using two portions of sulphuric acid, respectively ignite cool and weigh as sodium sulphate, the sodium found corresponds to not less than 9.2 per cent nor more than 9.4 per cent when calculated to the dried substance. Transfer about 0.2 Gm. of neo-Iopax to a Parr sulphur bomb, determine the iodine content by the Lemp and Broderick Method (Journal of the American Chemical Society 39: 2069), the amount of iodine found corresponds to not less than 51 per cent nor more than 53 per cent when calculated to the dried substance.

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
RAYMOND HERTWIG, Secretary

"RESISTANCE" CLAIMS IN FOOD ADVERTISING

Food advertising abounds with vague "resistance" claim. Certain foods or their constituents are alleged to increase resistance, implying, body resistance, which popularly signifies ability of the individual to keep well or healthy or not to suffer untoward effects from bacterial infections, fatigue, exposure to cold and wet, loss of sleep and the like.

A healthy body is free from disease, and its parts function normally. The tissues are physiologically sound, body cells function efficiently, there is a normal production of internal secretions or hormone, a normal power to produce immunity antibodies, and the many reactions of metabolism proceed without interference. Such a healthy body possesses a maximum resistance for the particular individual. Any influence disturbing its functioning, metabolism or structure may adversely affect resistance. The potency and duration of the disturbing factor determine the degree of the breakdown of resistance and consequent effect on health. Slight but insidious disturbances may continue a long time before signs of positive ill health appear.

Scientific clinical and common experience shows that adequate nutrition (water, minerals, vitamins, proteins, lipins, carbohydrates and roughage, adequate in kinds and amounts), exercise, rest, hygienic environment and sane habits are among the important requisites for maintaining "resistance" and the conditions of health. There are, however, many other intangible and undefined prerequisites.

It is apparent that resistance depends on many other factors than diet or any one dietary essential. Insufficiency of a dietary essential may eventually break down health, but more than is necessary of one or more of these essentials for adequate body reserves does not lead to a "super resistance."

Resistance produced by adequate nutrition is not to be confused with immunity resulting from antibodies in the body fluids produced by the body cells in their defensive reaction against pathogenic organisms and their toxins. Food advertising should conform to this established knowledge.

THE PASTEURIZATION OF MILK

Milk is an excellent medium for many dangerous bacteria as well as an excellent food for man. Disease germs may enter the milk directly from an ailing cow, be introduced by insects or be transferred to the milk by the fingers or mouth-spray of persons having to do with the collection or transportation of milk.

Once in the milk, some of the disease germs may multiply enormously. Extensive epidemics of typhoid, scarlatina, diphtheria, septic sore throat and other diseases are sometimes caused by contamination of milk supplies. Numerous cases of tuberculosis and undulant fever have been caused by raw milk.

Even when great care is used in overseeing the health of the cattle and of the milkers and in maintaining the cleanliness of the dairy, there remain many possibilities of contamination. A milkster may become overnight an unwitting carrier of some disease germ in his nose or throat, a typhoid carrier might be unknowingly employed in a most carefully conducted dairy.

Since disease germs are readily destroyed by well established methods of pasteurization, all milk for direct human consumption or for use in ice cream, cheese or other milk products should be pasteurized according to officially approved methods. After pasteurization the milk should be so stored and protected that it will not be contaminated. Liquid pasteurized milk should be retailed in sealed bottles.

The pasteurization of milk is a public health measure. The public should demand pasteurized milk for drinking and the use of pasteurized milk in milk products. The dairy trade should universally adopt pasteurization in the interest of public health.

There is no cogent evidence that pasteurized milk is significantly inferior nutritionally to raw milk.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULE AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

PROTEIN S M A (ACIDULATED)

Manufacturer—S M A Corporation Cleveland

Description—Spray dried homogenized mixture of skim milk soluble casein (sodium caseinate) beef fat coconut oil cacao butter, cod liver oil, potassium chloride salts lactic acid (derived by culture with *Streptococcus lacticus*) and fresh lemon juice, contains vitamins A, B, C, D and G.

Manufacture—The milk used is collected in accordance with provisions of the sanitary code amendment No. 9 of the Cleveland Board of Health (see this section for SMACO 206 Powdered Whole Milk, *THE JOURNAL* June 6, 1931, p. 1953). The milk is warmed to about 37 C and centrifuged for separation of milk fat. The skim milk (approximately 0.01 per cent milk fat) is pasteurized by the holding method and cooled immediately to 7 C or less.

Skim milk, soluble casein (see this section for SMACO 201 Liquid Protein Milk, *THE JOURNAL* March 4, 1933, p. 663) and S M A fat mixture (beef fat coconut oil cacao butter and cod liver oil) are mixed, pasteurized homogenized and cooled to 20 C or less. Pure culture of *Streptococcus lacticus* is added. The mixture is allowed to "ripen" until the acidity is approximately 0.75 per cent expressed as lactic acid and fresh lemon juice is added to bring acidity to a pH of 4.6. The entire mixture is spray dried and automatically canned in an atmosphere of nitrogen gas to prevent oxidation of the fat and vitamins.

The lemon juice is extracted from fresh fruit immediately before use and added to the factory mix immediately before the spraying operation to protect the vitamin C content.

Analysis (submitted by manufacturer) —

	per cent

	per cent
Ash	0.6
Fat (ether extract)	2.0
Protein (N × 6.38)	3.5
Lactose	2.8
pH	4.6

Calories—48 per gram 136 per ounce

Vitamins—Diluted according to instructions contains per quart

Vitamin A, 3,500 Sherman units

The B (complex) equals that of the milk and 20 cc of fresh lemon juice

Vitamin C approximates that of 20 cc of fresh lemon juice. Seven hundred and fifty A D M A (75 Steenbock) vitamin D units.

Claims of Manufacturer—A lactic acid (pure culture) antirachitic, antiscorbutic food for prematurely born and other infants requiring a high protein intake for the correction of nutritional disturbances.

HALES PRIDE TOMATO JUICE

Distributor—Hale-Halsell Company, McAlester Okla.

Packer—Gibson Canning Company Gibson City Ill.

Description—Tomato juice seasoned with salt retaining in high degree the natural vitamin content the same as Gibson's Finest Tomato Juice (*THE JOURNAL* Sept 16, 1933, p. 931).

CERTIFOODS CERTIFIED NURSERY FOODS—
SPINACH (SERVED)

VITAMIN CONTENT GUARANTEED, NO ADDED
SEASONING OR SUGAR

Manufacturer—Certifoods, Inc., New York, a subsidiary of the Maltine Company, New York

Description—Sieved spinach prepared by methods efficient for retention in high degree of the natural mineral and vitamin values no added seasoning or sugar.

Manufacture—Fresh spinach is cleaned washed, inspected, trimmed cut stem wilted, heated to 71 C, sieved in an atmosphere of nitrogen gas, canned, processed and packed as described for Certifoods Certified Nursery Foods—Green Beans (*THE JOURNAL*, Oct 3, 1931, p. 1003). The processing is for forty minutes at 116 C.

An alternative is the use of spinach that has been previously washed trimmed packed in No. 10 tins with hot water and processed for fifty minutes at 122 C. The canned spinach is subsequently treated as described above.

Analysis (submitted by manufacturer) —

	per cent
Moisture	95.0
Total solids	5.0
Ash	1.1
Fat (ether extract)	0.2

Calories—0.1 per gram 3 per ounce

Vitamins—The methods of preparation sieving and processing are efficient to conserve the natural vitamins in high degree.

The product is guaranteed to contain 560 units of vitamin A (Sherman method), 2 units of vitamin B (Chase and Sherman method) and 2 units of vitamin C (Sherman-LaMer method) per ounce.

Claims of Manufacturer—See this section for Certifoods Certified Nursery Foods—Green Beans (*THE JOURNAL*, Oct 3, 1931, p. 1003).

WHITE PEARL MACARONI ALPHABETS
WHITE PEARL MACARONI SHELLS
WHITE PEARL MACARONI RINGS
WHITE PEARL VERMICELLI

Manufacturer—Tharinger Macaroni Company, Milwaukee

Description—Alphabet, shell and ring macaroni and vermicelli prepared from durum patent flour and durum semolina the same as the accepted White Pearl Macaroni and Spaghetti (*THE JOURNAL*, April 23, 1932, p. 1455).

BEECH-NUT STRAINED SPINACH

(Slightly seasoned with salt)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved spinach retaining in high degree the natural vitamin and mineral values, seasoned with salt.

Manufacture—Canned California spinach specially put up without salt is strained and salt (0.5 per cent) is added. The subsequent treatment and processing are the same as for Beech-Nut Strained Carrots (*THE JOURNAL*, Nov 11, 1933, p. 1562).

Analysis (submitted by manufacturer) —

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SAURDAY, JANUARY 13, 1934

1934 SUBSCRIPTION AND DUES PAYABLE

For the convenience of those who have not yet paid their dues for 1934 or who have not yet completed their subscription to THE JOURNAL and the special periodicals published by the American Medical Association, a colored slip is enclosed in this issue. This statement is made in such form that it constitutes, when properly folded, a convenient envelop which does not require addressing or the affixing of postage stamps. When it is placed in any mail box in the United States it will be delivered to the headquarters of the Association, where the cost of postage is assessed.

There appears likewise in this issue an advertisement indicating some of the reasons why THE JOURNAL is necessary to the practicing physician, and also the special values associated with the publications in the specialties. Throughout the world, THE JOURNAL is recognized as the leading medical publication. In view of the material already in prospect for 1934, it is safe to say that the publication will advance during the year.

In addition to material derived from the annual session, THE JOURNAL has a choice each year from some three thousand voluntarily submitted manuscripts. Moreover several series of special articles are now in process of preparation. Physicians whose dues are not yet paid should, if possible, make prompt use of the colored slip and thereby ensure uninterrupted delivery of THE JOURNAL.

THE CLEVELAND SESSION

At a meeting held at the headquarters of the American Medical Association in Chicago recently, the Council on Scientific Assembly and the secretaries of the various sections announced some of the plans already made for the Cleveland session. These indicate the appearance of several new features as well as the maintenance of the extraordinary opportunities for graduate education in medicine that have been associated with previous meetings.

Prominent at the Cleveland session will be a series of General Scientific Meetings planned wholly for the advancement of the practitioner in subjects of current interest. For this purpose, clinicians and demonstrators are being chosen who have achieved note either for their special work on the topics to be discussed or for their pedagogic ability as demonstrated at various clinical meetings held throughout the country. In view of the now recognized wide dissemination of amebiasis and the extraordinary interest associated with the outbreak of a special form of amebiasis in two Chicago hotels during A Century of Progress Exposition, an entire afternoon of the clinical program is to be devoted to a complete consideration of this disease. In this program the leading investigators, epidemiologists and clinicians of the country will cooperate. At the same time, a demonstration in the Scientific Exhibit will make available opportunity for learning at first hand the steps in clinical and laboratory diagnosis of this disorder as well as the various drugs now available for treatment and the methods and routine of administration. Moreover, the Committee on Scientific Exhibit is planning a number of special exhibits in other fields, including particularly a demonstration of gross pathology with fresh material made available from Cleveland hospitals.

The secretaries of the scientific sections have been besieged by a deluge of requests for places on the program. In several sections more than two hundred applications have been received for the sixteen to eighteen places available. This indicates not only extraordinary interest in the session itself but an opportunity for the various sections to assemble programs of unusual merit.

Because of its central location and easy access, the Cleveland session should be one of the greatest ever held in the history of the Association. On previous occasions attendance at these sessions has been marked by the presence of from 5,000 to 7,500 physicians, representing by far the largest medical meetings held anywhere in the world. Since the facilities at Cleveland are exceptional, permitting all the meetings to be held under one roof, together with the scientific and technical exhibits, there is reason to believe that the Cleveland session may break all previous records for attendance.

Fellowship in the American Medical Association is a prerequisite to registration at the meeting. In this

issue of THE JOURNAL appears the usual slip for the sending of fellowship dues. Physicians should not delay in returning the slip since it is desirable that the records be fully in order well in advance of their attendance at the session.

EMERGENCY MEDICAL RELIEF AND THE CIVIL WORKS ADMINISTRATION

The innumerable activities of the government in relationship to medical practice during the emergency have been carefully recorded in preceding issues of THE JOURNAL. Through constant contact with authorities in Washington by representatives of the Bureau of Legal Medicine and Legislation through long distance telephone conversations with government officials and through special conferences held by various officers and committees of the Association with governmental bodies all this material has been assembled and published at the earliest possible moment. Every one officially representing the medical profession through the American Medical Association has been doing his utmost to secure a maintenance of the ideals of the medical profession in the organization of this work and at the same time to insure to the needy public the right type of medical service. How efficiently these various representatives have functioned is perhaps best demonstrated by the following letter sent with the latest information to be made available, by Harry L. Hopkins, who is at the same time administrator of Federal Emergency Relief and of the Federal Civil Works Administration. The letter reads in part:

The United States Employees' Compensation Act of 1916 as amended, requires that medical care be provided through United States medical facilities where these are available and adequate. This will be the case only in certain localities, chiefly in large cities. There is no intention of increasing Federal hospital bed capacity where existing facilities are not adequate.

The Civil Works Administration, as employer, knowing the high ethical standards of the American Medical Association, asks you to share the responsibility of providing the best medical care available, and securing the best possible end results for employees who incur injuries in the performance of their duties.

We wish to emphasize our recognition of the great service the medical profession has always rendered by freely giving medical care to the needy, and our especial appreciation of the profession's cooperation during the past few years in providing medical care for the unemployed, in many cases entirely without remuneration.

We shall rely upon the American Medical Association to do everything possible to secure wholehearted and disinterested cooperation from its member societies. We specifically urge that you solicit of your membership through editorials and at any forthcoming meetings, their cooperation.

HARRY L. HOPKINS
Administrator

In the special article concerning emergency medical relief and the compensation work for the Federal Civil Works Administration which appears under Association News in this issue, there is a memorandum from the United States Employees' Compensation Commission to state civil works administrators. It will be noted that

in this memorandum the government has affirmed again its confidence in the disinterested and public spirited attitude of organized medicine. It has requested the county societies, as the local organizations most immediately familiar with all of the medical profession, to include on their lists of physicians who wish to do this type of work well qualified members of the medical profession who may not be members of the county society. In this attitude the government expects the officials of the county medical societies to be fair, since it would manifestly not be just to omit the names of well qualified physicians who, for other than professional reasons, are not members of the county societies. It is, moreover, a question as to whether or not the government could officially fail to recognize the possibility that some qualified man might not hold membership.

Thus the government has put on the county medical societies, representing the functioning units of medical organization, the responsibility of proposing for such service only the names of physicians known to be well qualified by training and experience to handle the type of work involved. If any physicians are proposed for this service who fail to meet the requirements the responsibility will rest clearly on the county medical societies concerned.

Government authorities feel that, in order to be practical, the lists of physicians authorized to do this work must not be too extensive. This may require, in larger cities, some equitable selection of physicians from among those well qualified for the work, possibly based on the need of the physicians for the extra work during the emergency.

The government does not anticipate that the amount of medical service required to take care of injuries and diseases in the line of duty among workers of the Civil Works Administration will be exceedingly great. Indeed, because of the manner of selection of such workers, it is likely to be relatively small and specialized, as compared with the general medical care required for these 4,000,000 employees and their families.

Finally, as in all other government work, there will be required in this service a considerable amount of detail work in the filling out of forms, reports and records. Such forms are regularly used, however, in all types of insurance and compensation service and are recognized as necessary in the administration of compensation cases. For this reason the officials of county societies may render a special service to both the medical profession and the government by arranging special courses or other means for acquainting the group authorized to do such work with the forms, records and reports that are required.

Throughout the United States there is much confusion in relationship to these new activities of the government. Whereas some states have for more than a year been regularly engaging in cooperative effort for emergency medical care, other states have merely

reached the stage of establishing committees for conferences with relief administrators. Conditions differ so widely in different states that it is simply impossible for any one central authority either governmental or that represented by medical organization to outline any uniform scheme, fee schedule or other arrangement that would suitably care for the diverse conditions concerned. The American Medical Association has been alert in caring for the interest of the public and the medical profession in the development of these new regulations. Under the decisions that have been developed, it is possible for county medical societies to come to agreements with relief administrators and with officials of the Civic Works Administration that fill all the requirements of the various interests concerned. *THE JOURNAL* would emphasize again the importance of recognizing the emergency character of all these activities. The medical profession must insist on its ideals of personal medical care and mutual responsibility between patient and physician rather than any definite trend toward complete control of medical practice by the state.

POVERTY AND DISEASE

A report on national vitality, prepared many years ago by a governmental commission¹ pointed out that whatever diminishes poverty or increases the physical means of welfare has the improvement of health as one of its first and most evident effects. Therefore an important method of maintaining vital efficiency is to conserve natural resources—land, raw materials, forests and water. Only in this way can food, clothing, shelter and the other means of maintaining life be obtained. Conversely, the conservation of health will tend in several ways to the conservation of wealth. First, the more vigorous and long lived the race the better utilization can it make of its natural resources. The labor power of such a race is greater, more intense, more intelligent and more inventive.

In considering such problems of conservation as they affect human life, one usually thinks far more of mortality than of morbidity. The latter, however, has a serious bearing on public welfare. It has been estimated² that there are always about 3,000,000 persons in the United States on the sick list. Of these, approximately one third, or 1,000,000 persons, are in the working period of life. Without considering the effect of such conditions of life on the happiness of the population, a feature of the highest import in a social sense, the money cost of the illnesses involved, including such factors as loss of earning capacity and expenditures for care, amounts to hundreds of millions of dollars. It is stated, for example, that from tuberculosis alone the gross loss of earnings by illness and of potential earnings cut off by death, together with the expenses of ill-

ness, amounts to more than \$1,000,000,000 per annum. Of the sum mentioned, the loss to the consumptive themselves amounts to more than \$660,000,000, leaving \$340,000,000 as the loss to other members of the community. Obviously, if such costs are preventable there is alike a multiple advantage and an obligation to make vigorous efforts toward conservation of health—reduction of morbidity as well as of mortality. The call is for efforts to make life not only much longer but also more pleasant and efficient.

In writing of lengthening human life, Harris and Butt³ pointed out that there are no definite records to show whether or not the oldest persons living today have survived longer than the exceptional individual who lived many generations ago. The average length of human life is decidedly greater now than formerly, and the reduction in death rate has been particularly evident during the years that have intervened since science came to the rescue of mankind. While actual records of conditions prevailing during the middle ages are few, the best information indicates that the average length of life in Europe at that time was about 21 years as compared with 55 years in the United States today. Such records lead justifiably to the contemplation of how they have been attained.

It may not be comforting, but it surely is instructive to turn now and then to an objective contemplation of the problems that still remain in the field of health conservation. A stimulating illustration has just been reported from the heart of the Amazonian jungle. From Brazil Needles³ tells the story of a group of persons in the Amazon Valley who exhibit the acme of lethargy, shiftlessness and general lack of well being, for which they can scarcely be blamed. To help them it is necessary to realize the facts. According to Needles, the average native of the Amazon Valley is afflicted with what he has called the Amazonian pentad. The five major disabilities to which the "universal lethargy" is due are, in differing degrees of importance, (1) chronic malaria, (2) verminosis, (3) secondary anemia, (4) malnutrition and (5) splenomegaly.

To realize more adequately what this really involves, one must consider a few of the startling details. From various surveys "it is safe to state that the great majority of natives have chronic malaria." In more than 6,000 stool examinations for verminosis in a single hospital laboratory over a period of three and one half years, less than 700 negative observations were recorded. There are many multiple infestations. *Ancylostoma* is the most frequent invader, with *Trichuris* next and *Ascaris* third. Almost 90 per cent of those examined give evidence of suffering from secondary anemia. The explanation of some of the "lethargy" may be found in the widespread malnutrition. Needles has the impression that, while the diet lacks much of being ideally

¹ Fisher, Irving. Report on National Vitality, Its Wastes and Conservation. Bull. 30. Committee of One Hundred on National Health. Washington, D. C. Government Printing Office, July 1909.

² Harris, F. S. and Butt, N. I. Scientific Research and Human Welfare. New York, Macmillan Company, 1924.

³ Needles, R. J. Health Problems in the Amazon Valley. Science 78: 532 (Dec. 8) 1933.

balanced, the chief difficulty is not this so much as a less than normal quantity. The natives are for the most part miserably poor and unable to purchase enough for adequate maintenance. Here is a striking illustration of the vicious circle set up between poverty and disease, each of which tends to produce the other. That the situation is by no means hopeless is pointed out by Needles. "Where adequate mosquito control and adequate quinine are available, where venicufuges are freely and frequently given, and where the native has money with which to purchase adequate food, his physical status becomes remarkably better." A key to the opportunity for progress may be found in the words of a recent writer.² Physicians working throughout the ages were able to cope with infection and disease but imperfectly. It was only when trained research workers devoted themselves to a study of the fundamental causes of disease that real significant progress was made, more was then accomplished in a half century than in all the past history of the world.

Current Comment

ULTRAVIOLET THERAPY IN ORAL DISEASES

Because the promotional material for ultraviolet radiation apparatus includes odontologic claims as well as therapeutic claims intended primarily for the attention of the physician, the Council on Physical Therapy asked the Council on Dental Therapeutics of the American Dental Association to cooperate in the investigation of this form of therapy. After careful study, the Council on Dental Therapeutics reported that many of the claims were greatly exaggerated and that the evidence referred to in the promotional literature did not justify the dental profession in adopting ultraviolet radiation as a useful therapeutic agent. Furthermore, the dental council recommended that it was not wise for the dental profession to employ this treatment until more convincing evidence had been presented by the promoters and the enthusiasts to substantiate the claims made. In this issue of *THE JOURNAL* an abstract of the report mentioned appears in the columns of the Council on Physical Therapy. Briefly, the Council on Dental Therapeutics declares that the efficacy of ultraviolet radiation in connection with postoperative pain, following the extraction of teeth or other surgical procedures whether due to dry socket, infective osteitis or traumatism during local anesthesia, said to be readily suppressed by ultraviolet radiation, had not been established by critical research. The methods used to fix the diagnosis, the condition of the patient, the natural periods of remission and the response to other forms of treatment apparently were given no consideration whatever in these clinical writings. In conclusion, the Council on Dental Therapeutics reiterated that no adequately controlled evidence had been presented in the advertising matter or descriptive literature to warrant the use of ultraviolet radiation in the treatment of oral diseases and conditions.

HEIGHT OF FOREHEAD

It has recently been pointed out by the anthropologist Hrdlička¹ that, of all the various parts of the body, the forehead seems to have been neglected as to accurate measurements. This seems surprising, since the character of the forehead without doubt has played a large part esthetically in human relations, logically one might expect the height of the forehead to indicate cranial volume with some degree of accuracy and hence be correlated more or less directly with intellectual capacity. One of the difficulties has been to select reference points from which to make measurements. Hrdlička uses as the height of the forehead the difference between the chin-nasion height and the distance between the chin and the center of the arch of the hair line. To determine the correlation between the height of the forehead and intellectuality in males, measurements were made of 510 Old Americans with at least three generations American born on both sides of the family, of 118 Old Americans from the highlands of northeastern Tennessee, an extremely backward group, of 25 Old Americans, members of the National Academy of Sciences, and of 32 members of the same group, irrespective of nationality. (There were 118 members of the National Academy whose foreheads could not be measured owing to lack of hair over the forehead.) The maximum difference between the heights of the forehead in the four groups was found to be 0.02 cm, the average height of the forehead being 6.58 cm. This astonishing agreement between values for such divergent groups indicates the lack of correlation between the height of the forehead and intellectuality. Four groups of males representing different races were studied similarly, and the following average measurements were obtained: Old Americans, 6.59 cm; American Indians, 6.62 cm; full-blood young to middle-aged American Negroes, 6.98 cm; Alaskan Eskimos, 7.16 cm. Considering the character of the groups, the data show the fallacy of the idea that a high forehead in general indicates a high intellectuality or that it is a mark of racial superiority. Comparing the sexes in three important American races, it was observed that the height of forehead of the white woman is slightly lower absolutely but in relation to stature exceeds that of the male, absolutely and in proportion to body height the forehead of the Indian woman is decidedly lower than that of the male, in the Negro female the forehead is absolutely and in proportion to stature higher than that of the male. Such irregular variations in measurements according to sex are most unusual in anthropometry. It seems obvious that the height of the forehead as here defined bears little relationship to race, sex or the degree of intellectual attainment. Furthermore, this measurement appears to vary independently of the height of the frontal part of the skull. The obvious conclusion to be drawn is that it is definitely a function of the downward extension of the hair line which forms one of the points of measurement. The causes of the variation in position of the normal hair line have thus far not been determined.

Association News

MEDICAL AND HOSPITAL SERVICES FOR ILL AND INJURED EMPLOYEES OF FEDERAL CIVIL WORKS ADMINISTRATION

Four million five hundred thousand men and women have been given employment under the Federal Civil Works Administration since Nov. 16, 1933. They are being paid wages considered sufficient to enable them to provide, at their own expense, medical and hospital service for themselves and their families, such as may be necessary on account of ordinary illness and injury. Physicians and hospitals must therefore look to the individual men and women whom they serve for payment for such service. On a clear showing of necessity, federal emergency relief funds can be used to pay for medical service in such cases. That service however must be authorized by the proper state or local emergency relief administrator. Federal emergency relief funds cannot be used at all for payment for hospital service.

All civil employees of the United States including these employees of the Federal Civil Works Administration, and all employees of the District of Columbia except members of the police and fire departments, are entitled to medical and hospital service at government expense for all accidental injuries from which they suffer in the performance of their duties and for all diseases proximately caused by their employment. This prerogative they obtain under the provisions of the United States Employees' Compensation Act of 1916 as amended. The act provides:

That for any injury sustained by an employee while in the performance of duty whether or not disability has arisen the United States shall furnish to the employee all services, appliances and supplies prescribed or recommended by duly qualified physicians which in the opinion of the commission are likely to cure or to give relief or to reduce the degree or the period of disability or to aid in lessening the amount of the monthly compensation. Such services, appliances, and supplies shall be furnished by or upon the order of United States medical officers and hospitals but where this is not practicable they shall be furnished by or upon the order of private physicians and hospitals designated or approved by the commission.

Under the authority thus conferred the United States Employees' Compensation Commission has designated some 4,000 physicians in private practice to furnish medical service, when United States medical officers and hospitals are not available, to the 600,000 civil employees normally in the service of the United States government and the government of the District of Columbia. It has provided too, by regulation, that:

In localities where neither government hospitals nor dispensaries nor designated physicians are in the vicinity the injured employee or his official superior should secure treatment from the nearest available competent physician licensed to practice medicine and surgery. Such a physician need not be given any specific authority for treatment but should be informed that the commission will settle all reasonable charges for fees not in excess of those prevailing in that locality for patients receiving the average income of government employees.

The regulations promulgated by the United States Compensation Commission to govern medical and hospital service at government expense, for injured and ill federal employees entitled to such service, were supplemented, Nov. 27, 1933, by regulations promulgated by the Federal Civil Works Administrator applicable only to employees of the Federal Civil Works Administration. These regulations, however, were superseded by others issued December 12, but retroactive to November 16, so that the regulations of November 27 may be disregarded. These activities have been duly recorded in recent issues of THE JOURNAL. The regulations promulgated by the Federal Civil Works Administrator went further than those promulgated by the United States Employees' Compensation Commission by requiring that employees of the administration entitled to medical and hospital service at government expense be referred to available state, county or municipal hospitals and dispensaries when no federal medical facilities were available and that only in the absence of any such hospital or dispensary,

as well as the absence of federal facilities, should such an employee be referred to a designated or approved physician or private hospital. Under those regulations no physician not previously designated by the United States Employees Compensation Commission could be employed to treat a patient if a federal, state, county or municipal hospital, or a designated physician, was available.

To adjust the misunderstandings that arose out of the differences in interpretations of the act, of the regulations promulgated by the Compensation Commission, and of the regulations promulgated by the Federal Civil Works Administrator, and to insure as effective and fair distribution of medical and hospital services as practicable, conferences were held among representatives of the commission, the administration, the American Hospital Association, the Catholic Hospital Association, the Protestant Hospital Association, and the American Medical Association. As the result of those conferences instructions have been issued by the Compensation Commission that should go far toward accomplishing the ends sought. The present situation however, that denies to injured and ill employees free choice of the physicians who are to treat them and of the hospitals in which they are to be treated, can be corrected apparently only by act of Congress.

A copy of the instructions issued January 5, by the United States Employees Compensation Commission to state civil works administrators follows. The exact terms of the instructions concerning hospitalization that are to be issued by the commission are not available as we go to press but the terms of the working arrangement approved by the Compensation Commission and the Federal Civil Works Administration on the one hand and by representatives of the three hospital associations on the other, are shown in the appended extract from a memorandum that the associations named have undertaken to send to their respective member hospitals. The representatives of the hospital associations have appointed a committee to advise with the United States Employees Compensation Commission as occasion may require and to assist in adjusting any difficulties or misunderstandings that may arise.

Instructions Sent by the United States Employees' Compensation Commission to State Civil Works Administrators Concerning the Selection of Private Physicians for Compensation Work

The list of physicians and surgeons (Form CA 76), designated to provide treatment where Federal Government medical facilities are not available or are inadequate, was for temporary guidance only, as indicated by telegram sent December 22.

Please instruct your local administrations to consult the officers of their county or district medical societies at once to enlist the societies' cooperation as follows:

1. Ask them to share with you the responsibility of preparing a list of the local physicians authorized to provide treatment to supplement Federal Government medical facilities when these are not available or are inadequate. This list should include physicians in the locality (whether members of the local medical society or not) who are well qualified by training and experience to render compensation service, who are licensed to practice medicine in the state, and who desire to participate in this service under the regulations of the United States Employees Compensation Commission. These regulations provide for fees not in excess of those charged by physicians generally to patients in the same income class as the injured person.

2. Have them indicate on this list physicians who, by training and experience, are especially qualified to handle unusual and special types of cases.

3. Request that they work out with you a proper plan, mutually satisfactory, for distributing the compensation work among the physicians on the list in as equitable a manner as possible. Any plan should provide for the immediate treatment of emergency cases and for treatment by physicians well qualified to handle the particular type of case.

A cumulative record should be kept which will show the number of cases which have been assigned to each physician on the list

Memorandum Sent by Hospital Associations to Their Members

SECTION OF HOSPITALS

Civil Works Administrators will be instructed to use Federal hospital facilities as required by the United States Federal Employees' Compensation Act of Sept 7, 1916, wherever practically available and adequate, but there is no intention of increasing the bed capacity and equipment of Federal institutions or of interfering with availability for those whom they are primarily intended to serve

Furthermore, Civil Works Administrators will be instructed that this ruling shall not interfere with the prompt hospitalization of urgent cases

When Federal facilities are not available, the nearest suitable hospital will be used, suitability to depend on the following factors: proximity, type of service, e. g., whether the hospital is well qualified to handle the special type of case and general quality of service. Hospitals accepting Civil Works patients shall, thereby, be understood to agree to the stipulated rates

Public hospitals, other than Federal, will not be given preference but when they are used, physicians will be allowed to make charges for services, when such charges are permitted by their hospital regulations. The United States Employees' Compensation Commission will not attempt to send out from Washington any list of hospitals designated to serve, but will instruct the Civil Works Administrators to secure advice locally as to the suitability of hospitals, from one or more of the following sources: medical advisory committees which have already been set up under F. E. R. A. Rules and Regulations, No 7, hospital associations, hospital, health or similar councils, county medical societies, boards of public welfare and/or health

Physicians treating Civil Works Compensation patients will refer them to hospitals selected by such physicians, when they consider hospital care necessary. U. S. Employees' Compensation Commission reserves the right to have its medical representatives examine patients at the hospital, and examine the records of these patients and to cause the patients' removal when they consider it necessary in the interest of the patient or to prevent overcharge, etc. Hospital records of these patients shall be open to inspection by representatives of the U. S. Employees' Compensation Commission

Rates were agreed upon and it is understood that the charge is to include the day of admission, but not the day of discharge or death, that the bills already incurred for Civil Works' employees will be adjusted on the above basis that the hospital care, when recommended by the attending physician, must be approved in writing by Civil Works Administration officials or representatives of the U. S. Employees' Compensation Commission, that in emergency cases, where the patient is admitted before authorization is secured the hospital shall notify the office of the Civil Works Administration within forty-eight hours and obtain written authorization, that the hospitals participating will promptly provide the U. S. Employees' Compensation Commission with such reports, records, etc., as may be requested

THE CLEVELAND SESSION

Symposium, in the Scientific Exhibit, on the Treatment of Burns

There will be a symposium on the treatment of burns in the Scientific Exhibit at the Cleveland Session June 11-15, 1934 with the Section on Surgery, General and Abdominal the Section on Practice of Medicine and the Section on Pathology and Physiology taking part. The symposium will be composed of a group of exhibits taking up the various phases concerned with the treatment of burns. Persons desiring to take part may obtain applications for space from the Director Scientific Exhibit, American Medical Association 535 North Dearborn Street, Chicago

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 5 to 5:15 Eastern standard time (4 o'clock central standard time). The subject for Monday, January 15, is "Pure Foods and Drugs." The speaker will be Dr. Morris Fishbein, editor of THE JOURNAL. Subjects and speakers for subsequent broadcasts will be announced weekly in THE JOURNAL.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters)

The subjects for the week are as follows:

January 16 Causes of Illness
January 18 Health and Water Bills

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM

The subject for the week is as follows:

January 20 Respiration and the Lungs

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Medical Library Board—The Maricopa County Medical Society has formed a library board with the responsibility of developing and maintaining the medical library opened by the society in Phoenix early in 1932. Members of the board are Drs. Orville H. Brown, chairman, George E. Shields, secretary-treasurer, Fred G. Holmes, Louis C. B. Baldwin and Thomas W. Woodman. Dr. William Warner Watkins was elected librarian. At present an attendant is in the library from 11 a. m. to 3 p. m. and the hours will be lengthened later. The library has available about ninety medical journals and several hundred books.

ARKANSAS

Personal—Dr. Robert Q. Patterson has been appointed professor of dermatology at the University of Arkansas School of Medicine, succeeding the late Dr. William R. Bathurst.

Society News—Dr. Major G. Seelig, St. Louis, addressed the Pulaski County Medical Society in Little Rock, November 13, on "A Retrospect of Medical History."—The Southeast Arkansas District Medical Society was organized by physicians of Ashley, Chicot, Desha and Drew counties, November 28, at a meeting in McGehee. Officers elected are Drs. Henry T. Smith, McGehee, president, John S. Wilson, Monticello, vice president, and Matthew C. Crandall, Wilmore, secretary.

CALIFORNIA

Changes in Health Officers—The following changes in health officers have been announced by the state health department:

Dr. Joyce A. Albert of Newman, succeeding the late Dr. Howell V. Armistead.
Dr. James B. McGuire of Mount Shasta, succeeding Dr. Paul Wright.
Dr. Frederick C. Gregg, city health officer of Calexico, succeeding the late Dr. William T. Talbott.

Impostor Traveling Through the State—Physicians are asked to be on the alert for an impostor, James W. Carlisle, alias Charles B. J. Ness, who is traveling throughout California presenting fraudulent endorsements from life insurance companies. According to the state board of medical examiners, Carlisle requests physicians to give him \$25, so that their names will thereafter be included in a book known as the "Insurance Medical Directory."

Certified Clams—All persons who dig soft shell clams or who deal in them as wholesalers are required to hold certificates which set forth the wholesomeness of the product, in accordance

with regulations of the California State Department of Public Health, effective January 2. Uncertified clams in markets, stores, restaurants and other places will be subject to destruction. There exists in the state an imminent menace to the public health the board points out because the large areas of salt water bays where these clams are dug are polluted by sewage. Every clam bed must be registered with the state board. The regulations provide also that soft shell clams sold for bait purposes by persons or stores that purvey clams for human food shall also be from certified sources and fit for human food otherwise they are not to be handled. Clams sold for bait as in bait stores shall be distinctly marked 'clams for bait only and not for human food. Clams intended for human food shall not be placed or kept in polluted or unclean water.

COLORADO

Society News—Speakers before the Medical Society of the City and County of Denver December 19 were Drs. Philip W. Brown Rochester, Minn. on Anemias; Franklin G. Crough Hysterical Reactions Common in General Practice; William M. Perke Depressive Reactions Common in General Practice; and Charles A. Rymer Organic Reaction Types. —At a meeting of the Boulder County Medical Society in Boulder December 14 Dr. John G. Ryan Denver reviewed the diagnosis and treatment of arthritis and Dr. Atha Thomas Denver spoke on the preventive and corrective treatment of arthritic deformities.

Midwinter Graduate Clinics—The midwinter graduate clinics of the Colorado State Medical Society will be held in Denver January 17-19 with sessions at the Denver General, Denver Children's and Colorado General hospitals. In addition to clinics the preliminary program announces addresses by the following physicians among others:

Edward F. Dean Denver Beck Method of Drilling Ununited Fractures
John Andrew Longmont Treatment of Varicose Ulcers
William W. Haggart Denver Compressed Fractures of the Spine Without Cross Neurological Symptoms in Industrial Surgery
Rudolph W. Arnold Denver Cancer of the Thyroid
Theodore P. Sears Denver Hyperparathyroidism
Isadore D. Bronfin Denver Differential Diagnosis of Cancer of the Lung
Louis S. Trust Denver Amebic Dysentery
John G. Ryan Denver Rheumatoid Arthritis
William B. Yerge Denver Diagnostic Value of Liver Function Tests
Constantine F. Kemper, Denver Hormone Standards in Clinical Medicine
Royal H. Finney Pueblo Medical Care of Peptic Ulcer

DELAWARE

Society News—At a meeting of the New Castle County Medical Society in Wilmington December 19 Dr. Temple S. Fay, Philadelphia lectured on 'Practical Aspects of Dehydration.' —Dr. Arthur C. Morgan Philadelphia directed a conference on tuberculosis in Wilmington December 15, under the auspices of the Delaware Academy of Medicine.

Health at Wilmington—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million for the week ended December 30 indicate that the highest mortality rate (245) appears for Wilmington, and for the group of cities as a whole, 122. The mortality rate for Wilmington for the corresponding period last year was 162 and for the group of cities, 147. The annual rate for eighty-five cities for the fifty-two weeks of 1933 was 11, as against a rate of 112 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Cancer Control—The Delaware State Board of Health has made cancer a notifiable disease, making available special record forms for reporting cases. The recent establishment of tumor clinics in various hospitals in the state was the beginning of the active program of cancer control in Delaware (THE JOURNAL, Oct. 7, 1933, p. 1159). Dr. Douglas M. Gay, pathologist at the Delaware Hospital, Wilmington, has been appointed director of clinics, and a trained cancer worker supervises the follow-up work and record keeping. All records are centralized at the Delaware Hospital in charge of Dr. Gay. Seven clinics are contemplated, but diagnostic clinics are already under way at Lewes, Dover and Milford with treatment clinics now organized at the Delaware and Wilmington General hospitals. The program is in charge of a state committee of the American Society for the Control of Cancer composed of representatives of medical organizations, official agencies and laymen.

DISTRICT OF COLUMBIA

University News—Dr. Howard T. Karsner, Cleveland delivered the December lecture in the Smith Reed Russell series at George Washington Medical School on 'Rheumatic Heart Disease.' Prof. Max Bergmann, director of the Kaiser Wilhelm Institute in Dresden, Germany, lectured on 'Recent Work in the Chemistry of Proteins and Amino Acids' at the university, November 28.

ILLINOIS

Physicians Honored—The Springfield Medical Club honored Drs. George I. Stericker and Wilber P. Armstrong at a dinner meeting, December 19 in observance of their completion of fifty years in the practice of medicine. Dr. Stericker graduated in 1883 from Leeds School of Medicine in Leeds, England and Dr. Armstrong from Homeopathic Hospital College, Cleveland in 1884. Both physicians have sons associated with them in the practice of medicine.

Dental Hygiene—With the appointment of C. F. Deatherage, DDS, Chicago as state superintendent of mouth hygiene, the state department of health inaugurated a dental hygiene program that shifts the emphasis of educational activity from corrective to preventive work. L. I. Webb, DDS, Ashley has been appointed assistant to Dr. Deatherage. A better dietary is the chief objective of the program. The Illinois State Dental Society is cooperating through a committee that meets each month with the dental hygiene section of the state department of health.

Chicago

Personnel—Dr. Joseph Weltold has been appointed associate clinical professor in the department of genito-urinary diseases at Loyola University School of Medicine. —Dr. Charles F. Yerger has been promoted to associate clinical professor of ophthalmology at Loyola University School of Medicine. —Dr. Max Thorck has been elected a corresponding member of the Surgical Society of Madrid, Spain.

Change in Society's Programs—Dr. Francis A. Faught, Philadelphia will discuss medical economics and the Philadelphia plan before the Chicago Medical Society, January 1. Previously announced plans stated that Senator Royal S. Copeland, New York, would discuss the Copeland bill. In the symposium on the gallbladder in general practice, January 24 Dr. George W. Crile, Cleveland will present the surgical aspect instead of Dr. Everts A. Graham, St. Louis, as here before announced.

Memorial Meeting—The first official 'memorial meeting' of the Chicago Medical Society will be held January 14 at the Murphy Memorial Hall at 3 o'clock to honor the memory of members who died in 1933. The speakers will be Dr. James B. Herrick, president of the Society of Medical History who will review the life of Nathan Smith Davis, one of the founders of the Chicago Medical Society and the American Medical Association; and Preston Bradley, pastor, People's Church of Chicago, whose subject will be 'The Beneficence of Medicine.'

Course on Psychoanalysis—The systematic presentation of psychoanalysis is the theme of a course being conducted by Drs. Franz Alexander and Karen Horney at the Institute for Psychoanalysis. The titles of the lectures which began January 11 to continue on Thursday afternoons, are:

Nature of Psychological Understanding
Historical Development of the Main Concepts of Psychoanalysis
Concept of the Unconscious
Fundamentals of Psychic Dynamics (Repression, Regression, Reaction Formation, Sublimation)
Theory of Instincts
Theory of Dreams
Development of the Personality
General Concepts of the Structure of Neuroses and Psychoses
Principles of the Psychoanalytic Technique
Possibilities of Application of Psychoanalysis to Other Sciences

The Medical Park—Articles of incorporation were filed, January 3 as the first step toward the creation of a medical center in Cook County. With the objective of coordinating all the medical facilities in Chicago into one great medical center, it is planned to centralize in the vicinity of Cook County Hospital. Using the present facilities as a nucleus it is proposed to replace unrelated structures with new buildings and to improve the landscaping of the area. The purpose of the corporation, known as the Medical Park at Chicago is to promote and establish the medical center, effect passage of favorable legislation and arouse interest for the project. Among the directors are Drs. Bernard Fantus, Frederick Tice, Austin A. Hayden, Charles Davison and H. Edmond Quinn and Mr. Asa S. Bacon, superintendent of Presbyterian Hospital.

Sectional Meeting of Otolaryngologists—A joint session of the Chicago Laryngological and Otological Society and the middle section of the American Laryngological Rhinological and Otological Society was held at the Ambassador Hotel, January 9. The program was presented by the following:

- Dr. Howard C. Billinger: Bacteremia and Acute Upper Respiratory Infections
- Dr. William Mithoefer: Cincinnati Hypertonic Muscles of the Neck as a Cause of Headaches
- Dr. Harris H. Vul: Cincinnati Disease of the Sphenoid Sinus as a Cause of Reflex Pain in the Head
- Dr. Elmer W. Hagen: Anatomy and Pathology of the Petrous Bone Based on the Study of Fifty Temporal Bones
- Dr. Isaac A. Abt: Postangular Sepsis
- Leslie B. Grey, Ph.D.: The Crypt Systems of the Tonsils Throughout the Life Span
- Dr. John W. Carmack: Indianapolis Treatment of Lateral Sinus Thrombosis with Report of a Case of Canalization of the Sigmoid and Jugular Vein After Ligation
- Dr. Harry I. Pollock: Genuine Ozena in the Light of Recent Investigations

Arthur Isaac Kendall, Dr. P.H. professor of research bacteriology, Northwestern University Medical School was guest speaker at the dinner meeting on New Bacteriology.

INDIANA

Secretaries' Conference—The annual conference of secretaries of the component societies of the Indiana State Medical Association will convene in the Lincoln Hotel Indianapolis, January 21. Speakers will include:

- Dr. Harold Jackson Davis: Albany, N.Y. A Statewide Program for Medical Care to Indigent Persons in Their Homes Based on Federal Emergency Relief Administration's Rules and Regulations Number 7 and Data Drawn from Two Years' Experience in New York State
- Dr. William W. Bauer: director, Bureau of Health and Public Instruction, American Medical Association, Chicago. Duties of the Profession in Health Education
- Dr. Eldridge M. Shanklin: Hammond, Your Journal
- Dr. Nathan B. Van Ert: New York, Medical Economics
- Alphonse M. Schmitt: St. Louis, Business in the Practice of Medicine

Topics to be generally discussed will include the immunization and child health program, federal emergency relief act funds, and general activities of large and small county societies.

IOWA

Personal—Dr. William F. Boiler, Iowa City, was named president of the Iowa Academy of Ophthalmology and Otolaryngology at its recent annual clinical conference. Dr. William B. Armstrong has been appointed school physician of the Ames public schools, succeeding Dr. Andrew Ritan, who held the position for three years.

Society News—At a meeting of the Taylor County Medical Society, November 14, Drs. John C. Parsons and Carl E. Sampson, both of Creston, spoke on 'Sphygmomanometry in Cardiac Disease' and 'Diagnosis and Treatment of Mastoid Infections,' respectively. A symposium on tuberculosis was presented before the Woodbury County Medical Society, November 23, by Drs. Robert H. McBride, Howard I. Down and Mark C. Wheelock, Sioux City. The Davis County Medical Society was addressed, November 14, in Bloomfield, by Drs. Conda C. C. Heady on 'Progress of Medicine in the Last Forty Years' and William L. Downing, Moulton, 'Appendicitis.' Dr. G. Earl Garside, Chicago, spoke before the Black Hawk County Medical Society in Waterloo, November 21, on 'Intra-Abdominal Complications of Appendicitis.' Dr. James G. Carr, Chicago, spoke before the Scott County Medical Society, Davenport, December 5, on cardiovascular diseases and cardiac pain. Dr. Claude F. Dixon, Rochester, Minn., addressed the society, November 7, on 'Surgical Management of Cancer of the Colon.' Dr. Gabriel S. Westly, health officer of Manly, was elected president of the Iowa Public Health Association at its annual meeting in Des Moines, November 22.

LOUISIANA

Graduates from Foreign Schools—The Louisiana State Board of Medical Examiners, New Orleans, adopted a resolution, recently, requiring every physician from a foreign medical school to have, in addition to a foreign diploma, one from a medical college located in the United States and recognized by the board. The regulation was effective December 7.

Personal—Dr. Hiram O. Barker has been appointed superintendent of the Baptist Hospital, Alexandria, effective December 1, succeeding Mr. Edward Groner, who has resigned to become associated with the Southern Baptist Hospital, New Orleans. Dr. Carl C. Dauer has been appointed instructor in preventive medicine at Tulane University of Louisiana School of Medicine, New Orleans.

First Award of the Matas Medal—The Matas Medal for Vascular Surgery, named in honor of Dr. Rudolph Matas, emeritus professor of general and clinical surgery, will be awarded to Dr. Mont R. Reid, Cincinnati, January 23, in New Orleans. The medal will be provided through the Violet Hart Fund, which was created by Mr. Mike S. Hart in memory of his sister. The establishment of the award is a fulfillment of a request of Miss Hart, who was a patient of Dr. Matas. The fund will be administered by Tulane University and is to provide an award, to be known as the Rudolph Matas Award, to be made to that North American surgeon who has contributed outstanding work in vascular surgery. It is to be awarded as the occasion arises by a committee of surgeons selected by the Hart family and including the head of the department of surgery in Tulane's undergraduate school of medicine. The committee that selected Dr. Reid as the first recipient of the medal was composed of Drs. Emile Bloch, chairman, Lucian H. Landry, Isidore Cohn and Edward W. Alton Ochsner. Dr. Matas will personally present the award to Dr. Reid, who is Christian R. Holmes professor of surgery in the University of Cincinnati School of Medicine, Cincinnati. Fifteen years after his graduation from Tulane, in 1880, Dr. Matas returned to his alma mater as professor of surgery. He retired from active teaching at the institution in 1927.

MASSACHUSETTS

Personal—Dr. William E. Curtin, Plymouth, has been appointed medical examiner of the Third Plymouth District. Dr. Edward W. Whitney has been appointed superintendent of Northampton State Hospital, succeeding the late Dr. Theodore A. Hoch. Dr. Whitney has been assistant superintendent since 1917.

New Institute of Pathology—The Mallory Institute of Pathology of the Boston City Hospital was dedicated, December 13. It is named in honor of Dr. Frank Burr Mallory, who was pathologist from 1908 until his retirement last year, having been associated with the laboratory since 1891, when he was appointed assistant. The new building is the outgrowth of the old pathologic laboratory opened in December, 1895, and consists of a basement, four main floors and a penthouse. Quarters have been provided for the medical examiner service, which has been affiliated with the department for several years. According to the *American Journal of Pathology*, the medico-legal relation of the hospital received its first notice in the annual report of 1871 with a reference to the establishment of facilities for the reception and identification of unknown dead. Thus the purpose of the Mallory Institute of Pathology is to conduct routine pathologic and bacteriologic work of the Boston City Hospital and to investigate cases referred to the medical examiner's office of Suffolk County, South, in conjunction both with undergraduate and with graduate teaching.

MICHIGAN

New Department of Epidemiology—For the purpose of research in the control of communicable disease, a department of medical epidemiology has been added to the W. K. Kellogg Foundation, effective January 1, newspapers report. Dr. John E. Gordon, Detroit, will be in charge of the new department. Stress will be placed at present on the communicability of scarlet fever.

Dr. Kahn Awarded Prize—The American Association for the Advancement of Science at its winter meeting in Cambridge, Mass., December 31, voted its eleventh annual award of \$1,000 to Reuben L. Kahn, Sc.D., assistant professor of bacteriology and serology, University of Michigan School of Medicine, Ann Arbor, for his paper on "Tissue Reactions in Immunity," which presented experimental evidence of a new immunity principle. Dr. Kahn is prominently known for his discovery of the Kahn precipitation test for syphilis. He is 46 years of age and a native of Kovno, Lithuania. He received the degrees of bachelor of science from Valparaiso University, Indiana, in 1909; master of science from Yale in 1911; and doctor of science from New York University in 1916. He has been associated with the University of Michigan since 1928 as assistant professor and director of clinical laboratories of the University Hospital. He was bacteriologist with the New York Health Department 1913-1914; research chemist of the Hariman Research Laboratory, 1916-1917; and immunologist of the Michigan State Department of Health, 1920-1928. He served during the World War as lieutenant and later as captain in the U. S. Army Sanitary Corps, and is now a major in the medical reserve corps.

MISSOURI

President a Second Time—The inauguration of Dr. John C. Morfit as president of the St. Louis Medical Society took place, January 2. This is the second time he has held this office, having been elected first in 1907. It is the first time in forty-eight years that a physician has been recalled to the presidency of the society, although its records show that five other ex-presidents have been chosen two or more times. Dr. Bernard G. Farrar the first president was elected twice, 1836 and 1837. Dr. Hardage Lane the second three times, 1838, 1839 and 1847. Dr. Meredith Martin the fourth four times, 1840, 1842, 1845 and 1865. Dr. Thomas Rayburn the eleventh, 1854 and 1857 and Dr. Elsie Gregory, the twenty-fourth twice 1871 and 1886. Dr. Morfit is the sixtieth president.

Society News—Speakers before the Jackson County Medical Society, December 12, were Drs. David S. Dunn and Joseph Lawrence Jones on 'An Original Method for Internal Examination of the Neck of the Uterus and Its Clinical Application,' and Claude J. Hunt 'Resection of the Stomach for Carcinoma.'—Speakers before the St. Louis Trudeau Club, December 7, were Drs. David P. Burr on 'Uses and Abuses of Oxygen and Carbon Dioxide Therapy,' and Francis M. Pottenger, Monrovia, Calif., 'Clinical Aspects of Visceral Neurology of Lungs and Pleura.'—Henry I. Vaughan, Dr. P. H., health commissioner of Detroit, addressed the St. Louis Medical Society, December 15 on 'Preventive Medicine from the Family Physician.'—Dr. Charles L. North, New York, spoke before the St. Louis Medical Society, November 14, on 'Milk Sanitation and Its Effect on Public Health.'

NEVADA

Society News—Dr. Francis M. Pottenger, Monrovia, Calif., addressed the Washoe County Medical Society and members of the Nevada Public Health Association and State Nurses Association, Reno, November 14, on progress in the study of tuberculosis. He conducted a clinic at St. Mary's Hospital.

NEW JERSEY

Society Fifty Years Old—The Cape May County Medical Society celebrated its fiftieth anniversary at a meeting in Ocean City, November 14. A feature of the observance was a display of articles used by physicians of pioneer days among them a sword and cane presented by George Washington to Dr. John Dickinson said to have been the first physician in the county. One of the three surviving charter members, Dr. Eugene W. W., Sea Isle City, was present. Dr. James H. Ingram is in Peiping, China and the third living charter member, Col. Charles M. Grady, Ocean View, was unable to be present. Dr. Walter I. Illie, Philadelphia, made the principal address of the occasion.

NEW YORK

Personal—Dr. and Mrs. Francis Park Lewis and Mrs. Burr H. Nicholls, Buffalo, gave a reception at the Hotel Statler, January 1, in honor of their father, Mr. John Wesley Lewis, on the one hundredth anniversary of his birth.—Dr. Herbert U. Williams, professor of pathology and bacteriology, University of Buffalo School of Medicine, is on leave of absence until March, to visit the Philippine Islands and the East Indies.

New York City

Queens County Society Wins Immunization Award—The Bronx County Medical Society presented the Interborough Antidiphtheria Silver Trophy to the Queens County Medical Society at a ceremony in the offices of the health department, December 8, as the climax to an immunization campaign in the two boroughs (THE JOURNAL, Sept. 23, 1933, p. 1007, and Oct. 14, 1933, p. 1843). Bronx County lost by a slight margin in the contest.

Society News—Dr. Jean A. Curran addressed the Medical Society of the County of Kings, December 19, on 'Problems of Amebiasis,' and Dr. Warren L. Duffield showed motion pictures of the Lindbergh expedition to Labrador, Greenland and Iceland which he accompanied as medical adviser.—Dr. Armitage Whitman, among others, addressed the Ocean Medical Society, Brooklyn, November 20, on early diagnosis of orthopedic conditions.

Symposium on the Pituitary Gland—The Contin Society of the New York Homeopathic Medical College and Flower Hospital presented, December 16, the S. Franklin Adams Memorial Symposium on Metabolism. The subject was 'The

Pituitary Gland' and the participants were Drs. Abraham Rosenthal, who discussed the physiology and pathology, Linn J. Boyd, diagnosis, Philip J. R. Schmahl, medical treatment, and Karl Winfield Ney, surgery.

Illegal Practitioner Sentenced—Arthur Joseph Talamo, Brooklyn, was sentenced, December 11, to serve sixty days in the workhouse for having practiced medicine without a license. Talamo was licensed in New York in 1921, but this license was revoked the following year after it was shown that he obtained it with forged credentials from the University of Maryland Medical School. Using a different name, he had obtained a law student's qualifying certificate and had passed the bar examination but had not yet been admitted to the bar, as his case had not been passed on by the character committee. It was charged that Talamo paid Talamo \$50 for medical advice for his wife.

Dr. Goldwater Appointed Commissioner of Hospitals.—Dr. Sigismund S. Goldwater, hospital administrator, has been designated commissioner of hospitals of the New York Health Department succeeding Dr. John G. William Greeff. Dr. Goldwater was superintendent of Mount Sinai Hospital from 1903 to 1916, and director from 1917 to 1929. He was commissioner of health of New York City from 1914 to 1918 and, in 1908, municipal expert in hospital construction and administration of New York. In 1908 he was president of the American Hospital Association, in 1913, vice president of the New York Academy of Medicine, 1918-1921, vice president of the National Institute of Social Sciences and from 1924 to 1926, president of the American Conference on Hospital Service. He was medical counselor of the U. S. Veterans' Bureau in 1924.

OHIO

Personal—Dr. William H. Wenning, Cincinnati, was guest of honor at a dinner given by the Cincinnati Obstetrical Society, December 14, celebrating his fiftieth anniversary as a member of the society.

Historic Kidney Specimens—Three sections cut from the only three kidneys remaining which were described by Richard Bright were recently presented to the department of physiology of the University of Cincinnati College of Medicine by the nephritis clinic of Guy's Hospital, London. Physicians interested are invited to visit the department to see the specimens. One is stained with methyl violet to show amyloid changes and the other two with hematoxylin and eosin. The first was described by Bright in 'Reports of Medical Cases' in 1827 and the others in 'Guy's Hospital Reports' in 1838.

Promotions at the University of Cincinnati—The board of directors of the University of Cincinnati College of Medicine announced the promotion of Drs. Charles A. Helling Jr. and Horace W. Reid to assistant professors in the department of ophthalmology among other changes. Dr. Merrick F. McCarthy was advanced to associate professor of otolaryngology. A gift of \$25,000 from the estate of the late Mrs. Mary Hyndman to establish the James Gilmour Hyndman Fellowship in preventive medicine was announced. Dr. Hyndman was a member of the faculty of the college for several years before his death.

OKLAHOMA

Annual Banquet—The Ottawa County Medical Society held its annual banquet and homecoming in Miami, December 22, with physicians of the adjacent areas of Missouri and Kansas as guests. Addresses were made by Drs. Edward H. Skinner, Kansas City, Mo., on 'Cancer of the Cervix Uteri—Prevention and Treatment,' Charles C. Denme, Kansas City, Mo., 'Approach to the Treatment of Syphilis' and G. Fowler Border, Mangum, 'Thirty Years of Active Practice of Medicine.' Other guests made three minute talks.

PENNSYLVANIA

County Appoints Psychiatrist—Dr. Mary R. Bowman, Mount Joy, has been appointed psychiatrist and superintendent of service in connection with a new probation and parole system in Lancaster which was to have been effective January 1. It is expected that the system organized with the cooperation of the county commissioners, will facilitate the work of the criminal court.

State Tuberculosis Meeting—The annual conference of the Pennsylvania Tuberculosis Society will be held in Harrisburg, January 23-24. Among speakers will be Drs. Allen W. Freeman, Baltimore; Adrian V. S. Lambert and Kendall Emerson, New York, and Donald Guthrie, Sayre. Subjects

for discussion include school health programs, application of thoracic surgery in pulmonary tuberculosis and evaluation of tuberculosis programs.

Philadelphia

Cancer Records Presented to University—Frederick L. Hoffman, LL.D., Newark, N. J., consulting statistician, has presented to the Cancer Research Laboratory of the University of Pennsylvania his entire collection of material on cancer and collateral medical and vital statistics for permanent preservation and more convenient access to cancer workers. *Science* reports: "The collection includes data and statistics collected during the past fifteen years in association with the Prudential Life Insurance Company. Dr. Hoffman will move to Philadelphia and will have his office at the Cancer Laboratory."

Society News—The Philadelphia County Medical Society is to receive the medical and dental library of the late Luther Ashley Faught, DDS, father of Dr. Francis Ashley Faught. The collection will be placed in a separate library and named for the donor.—Dr. Wade H. Brown, New York, addressed the College of Physicians of Philadelphia, January 3, on "Hereditary Constitutional Peculiarities and Dietary Deficiencies."—Drs. John B. Montgomery and John T. Farrell, Jr., among others, addressed the Obstetrical Society of Philadelphia January 4 on "The Value of Postoperative Irradiation in Treatment of Carcinoma of the Ovary."—Dr. Cornelius G. Dyke, New York, addressed the Philadelphia Roentgen Ray Society, January 4, on "The Anatomy and Pathology of the Brain and Meninges, as Revealed by the Encephalogram."

TEXAS

Graduate Clinics—Baylor University College of Medicine, Dallas, is conducting graduate clinics for Texas physicians the first week-end in each month. Clinics are conducted at Baylor Hospital and scientific exhibits are shown in the Medical Arts Building. A wide variety of subjects is covered, varying each month. All ethical physicians are invited and no fees are charged.

Society News—Drs. Harold M. McClure, Chickasha, Okla., and Percy K. Smith, Wichita Falls, addressed the Wichita County Medical Society, November 14, on diagnosis in gynecology and Hodgkin's disease, respectively.—Dr. Eugene P. Norwood addressed the Navarro County Medical Society, Corsicana, December 4, on "Sinusitis Complicating the Acute Infectious Diseases."—The library of the El Paso County Medical Society has recently been placed in a special room connected with the headquarters of the city-county health department. It contains about 5,000 volumes.—The Panhandle (Third) District Medical Society held its semiannual session at Plainview, October 24-25 with the following speakers among others: Drs. James B. Coston, St. Louis, on "Agranulocytosis, Appearance of Early Pharyngeal Lesion" and "Diagnosis of Some Deceptive Head and Ear Symptoms"; Kenneth J. Wilson, Oklahoma City, Okla., "Trichomonas Vaginalis"; Harry Wilkins, Oklahoma City, "Diagnosis of Brain Tumors"; George H. Kimball, Oklahoma City, "Plastic Harelip."

VIRGINIA

Seaboard Medical Association in Norfolk—Dr. Paul F. Whitaker, Kinston, N. C., was elected president of the Seaboard Medical Association of Virginia and North Carolina at the annual session in Norfolk, December 5-7, and Dr. Clarence Porter Jones, Newport News, reelected secretary. Two public meetings were held, at which speakers included Drs. Walter E. Dandy, Baltimore, on "Treatment of Pains and Other Disturbances of the Cranial Nerves"; William H. Sebrell, Jr. of the U. S. Public Health Service on pellagra, and Rolla E. Dyer of the public health service on the Eastern type of Rocky Mountain spotted fever. Dr. Louis Hamman, Baltimore, addressed the scientific sessions on practical methods in examination of suspected heart disease.

GENERAL

Bequests and Donations—The following bequests and donations have recently been announced:

Mount Sinai Hospital, New York, \$1,000 by the will of Max Kops.
Beth Israel and Mount Sinai hospitals, New York, \$7,500 by the will of Otto Marx.
Chillicothe Hospital, Chillicothe, Ohio, \$5,000 under the will of the late Arthur B. Howson.
Huntington L. I. Hospital, \$10,000 by the will of the late Willard N. Byrles.
Mount Sinai and Montefiore hospitals, New York, \$7,500 each.
Lenox Hill, Lebanon Joint Diseases hospitals and the Tuberculosis Prevention for Children, New York, \$3,000 each by the will of the late Henry Ollesheimer.

Impostor in Prison—An impostor with many aliases, the most common of which are George Stanley Paris, George I. Paris, George Samuel Isaacman and Samuel Paris, is now in Folsom Prison, Folsom, Calif., serving an indeterminate sentence of not more than fourteen years, according to the California State Board of Medical Examiners. Paris was arrested in Los Angeles on a charge of passing worthless checks. In his travels about the country within recent years, Paris applied at various hospitals for staff membership claiming to be a licensed physician in California with reciprocal licensure in other states. No record has been found to show that he has ever attended a medical school or received a license to practice. Although records of the California State Board of Medical Examiners show that he did serve as an intern at Windsor Hospital, Glendale, Calif., which is not accredited. Paris served a short term in the Missouri State Prison in 1928 for obtaining money under false pretenses, and, in 1931 and 1932, a term in Alcatraz Island Prison (California) for desertion. Accounts of Paris's activities appeared in *THE JOURNAL*, Sept. 3, 1932, page 841, Aug. 6, 1932, page 484, and April 29, 1933, page 1351.

Society News—Dr. Theodore H. Weisenburg, Philadelphia, was elected president of the Association for Research in Nervous and Mental Disease at the annual meeting in New York, December 28-29. Drs. Lewellys F. Barker, Baltimore, and Clarence A. Patten, Philadelphia, were chosen vice-presidents and Dr. Thomas K. Davis, New York, was reelected secretary. The general subject discussed was "The Biology of the Individual." Among the speakers were Floyd H. Allport, Ph.D., Syracuse, N. Y.; Drs. William Healy, Roy G. Hoskins and Charles Macfie Campbell, Boston; Wingate Todd, Cleveland; Eugen Kahn, New Haven, Conn.; Charles R. Stockard and Walter Timme, New York.—Dr. William F. Braasch, Rochester, Minn., was elected president of the Clinical Society of Genito-Urinary Surgeons at its meeting in Iowa City, November 17-18, and Dr. Henry G. Bugbee, New York, was reelected secretary.—Dr. David M. Davis, Phoenix, Ariz., was chosen president-elect of the Medical and Surgical Association of the Southwest at the annual meeting in El Paso, Texas, in December. The 1934 convention will also be held in El Paso.—The sixty-third annual meeting of the American Public Health Association will be held in Pasadena, Calif., September 3-6.

FOREIGN

Health Institute for Tokyo—The Japanese cabinet has accepted the offer of the Rockefeller Foundation to donate 4,000,000 yen (about \$1,240,000) for the establishment of an institute of public health in Tokyo, the *Chicago Tribune* reports. The institute will be for the training of hygiene workers.

University News—A new department of preventive medicine has been opened at the University of Bristol with Dr. Isaac Walker Hall as director of laboratories and Dr. R. H. Parry, honorary professor of preventive medicine. Under an agreement with the city, the department will carry on the municipal bacteriologic, pathologic and preventive medical work.

Fiftieth Anniversary of Australian Medical School—The fiftieth anniversary of the Medical School of the University of Sydney, Australia, was celebrated, September 29. Sir William Cullen, chancellor, Dr. C. Bickerton Blackburn, dean of the medical school, and Dr. A. E. Mills reviewed the history of the school, pointing out that about 90 per cent of the physicians practicing in New South Wales are its graduates. The first class was graduated in 1888 and the first adequate building was opened in 1890. In the half century, 2,293 graduates have passed through the school. Little opportunity for research was available until a recent bequest provided for several full time professorships and direction of research. To accommodate the new departments the Rockefeller Foundation made the university a gift of a new building, which was opened September 28 as part of the jubilee ceremony. The building, which was erected at a cost of £100,000, has five floors, providing quarters for the departments of medicine, surgery, pathology, obstetrics and bacteriology, a library and a museum of pathology, with ample laboratories.

CORRECTION

Fever Therapy of Neurosyphilis—In the ninth line of the closing discussion by Dr. J. R. Driver in *THE JOURNAL*, Dec. 23, 1933, page 2020, following "103.5 F" the following words should be added: "A second dose of 25 millions was then given, followed two hours later by a peak temperature of 109.4 F." The discussion then goes on to say that this high fever was accompanied by convulsions and unconsciousness lasting for four hours.

The Tax on Insulin

The demand of British chemical manufacturers for a 33 per cent tax on imported insulin instead of the standing 10 per cent, was reported in a previous letter. An outcry against the iniquity of increasing the cost of insulin to diabetic patients, many of whom can ill afford to pay the present price was made in a liberal paper the *Star*. It received no support in the medical press which is evidently afraid to touch the question because of its bearing on the free trade controversy, generally regarded as political though really purely economic. The Board of Trade Tribunal which has been appointed to decide on all applications for tariffs heard the application for the increase. This was made by all the leading drug manufacturers. The point that was contested before the tribunal was not the effect of the tariff on the price but whether insulin was a fine chemical. It was necessary for it to come into this class for the imposition of the tariff. Prof E. I. Armstrong, a chemist, said that he did not regard insulin as a chemical but as a protein. It was argued that insulin was no more a chemical than floss was silk. A majority of the tribunal decided that insulin and its salts must be regarded as chemicals liable to duty. The tax will therefore be increased. The British manufacturers stated that they had no intention of raising the price if the duty should be imposed. But the question Why do they want the power to charge 33 per cent more than the price at which insulin can be imported? does not seem to have occurred to any one. No doubt they will not increase the price of insulin—for the present. The scandal would be too great. But improved methods have already reduced the price of insulin, and if the foreign manufacturers—Danes in this case—succeed in further improving their methods and further reducing their price, the English manufacturers need not under the tariff, move in unison with this. They can continue to charge anything up to 33 per cent above the Danes. The statement of the British manufacturers has only a temporary value. For people who cannot or will not understand economics—the great majority of even the educated in this country just now—it may be pointed out that the whole experience of the protectionist countries of the world shows that tariffs always raise prices.

The Rat Problem

Dr C. F. White, port of London health officer described at the Royal Sanitary Institute the measures taken in the Thames to prevent an outbreak of plague. All dead rats were sent for bacteriologic examination and the authorities were constantly sampling the live rat population of ships and shore premises. He did not believe that there was any danger of an epidemic of human plague in this country, but limited rodent plague might occur, with possibly a few human cases. Though a number of kinds of flea are capable of carrying plague, one particular flea, *Xenopsylla cheopis*, is the principle danger so that the 'cheopis index' of a port is a measure of the danger. With an index of a port below 1, there is little danger of rat plague spreading. Last year 728 fleas were caught ashore in the port of London and examined without a single *Xenopsylla cheopis* being found. This year two were found. Thus the danger of plague is very small. However it is considered essential to keep the rat population down and to eliminate nesting and breeding places. Only one measure is permanently effective against rats—rat proofing, which means

not only eliminating nesting and breeding places but making food and water supplies inaccessible.

The rat referred to is the brown rat, which in England has largely replaced the old English black rat. The latter is held to be responsible for the plague epidemics of former times which caused the death of a large part of the population of London. The black rat lives in houses and therefore in much closer association with man than the brown rat, which inhabits sewers but raids houses. Hence the black rat is much more dangerous than the brown rat as a carrier of plague. Mr M. A. C. Hinton, deputy keeper of zoology at the British Museum, has pointed out that there is a growing danger of the revival of the black rat population. The modern rat proofing is tending to shut out the brown rat, but the black rat has been encouraged by the establishment of kitchens on top floors illuminated by means of open skylights linked up roofs and streets bridged with telephone wires and cables. At night, processions take place along the cables and over the roofs and new colonies are established. Mr Hinton holds that the swift progress made by this species in colonizing the new London in the last thirty years has given rise to risk of the recrudescence of plague.

The Reform of Medical Education

A conference under the presidency of Lord Dawson, president of the Royal College of Physicians and medical representative of the Universities of Oxford, Cambridge and London and of the Royal Colleges of Physicians and Surgeons has undertaken the task which has heretofore defied the authorities of remodeling the medical curriculum. They have to consider all the new methods of treatment such as psychoanalysis, physical medicine and manipulative surgery. In a press interview the president stated that while the conference realizes that students should have the advantage of the new knowledge it is even more essential that they should be trained to use their intelligence by being given a grounding in the general principles of their profession and not merely a smattering of a great variety of branches.

Decline in Convictions for Drunkenness

The total annual convictions for drunkenness in England and Wales have decreased from 43,343 in 1931 to 30,146 in 1932 a reduction of over 28 per cent. This is the lowest figure recorded excepting the war year of 1918. Convictions for drinking methylated spirit, however show a slight increase but the number recorded (596) is trifling.

Robert Pugh Rowlands

Robert Pugh Rowlands, senior surgeon to Guy's Hospital and a former vice president of the Royal College of Surgeons has died suddenly. A Welshman, born at Towyn, he had a brilliant career as a student at Guy's Hospital, winning gold medals in anatomy, medicine and surgery. He passed through the appointments of demonstrator of anatomy and surgical registrar and joined the surgical staff of the hospital in 1906. An indefatigable worker he soon gained a high reputation as a surgeon and as an author. W. H. A. Jacobson who had been his teacher got him to collaborate in preparing the fifth edition of his standard work "The Operations of Surgery." Rowlands published valuable articles on the treatment of appendicitis and various abdominal conditions and became recognized as an authority on the surgery of the gallbladder. In 1929 he delivered the Bradshaw lecture before the Royal College of Surgeons on the Surgery of the Biliary Tract.

John Joly

The death at Dublin at the age of 76 of John Joly, professor of geology and mineralogy in the university removes a dis-

tinguished scientist who, though not a member of the medical profession, rendered great services to it by his researches on radium. His work on radioactivity in geology furnished the solution to several pressing problems such as the age of rocks, and has been claimed to be as fundamental in stratigraphical geology as was the work of Darwin in biology. He also calculated the age of the earth by means of the sodium content of the ocean. He contributed to the theory of the ascent of sap in plants and explained on philosophical grounds the bright colors of alpine flowers. In association with a surgeon the late Walter Stevenson of Dublin he introduced the deep seated use of radium in hollow needles which effected a revolution in radium therapy and became known over the world as the Dublin method.

PARIS

(From Our Regular Correspondent)

Nov. 29, 1933

The French Congress of Therapeutics

IN THE JOURNAL, JANUARY 6 page 55, an account was given of the sessions of the section of medicine of the French Congress of Therapeutics. To continue that report. The section of pharmacodynamics was devoted to a consideration of epinephrines. Professor Tiffeneau explained the chemical composition of epinephrines and the peculiar action of the amino group, the alcohol group and the side chain that enters into their composition. Mr Dorlencourt described the effects of epinephrine on the organism. Mr Tournade referred particularly to intracardiac injection which is adapted to late syncope due to anesthetics but not to a syncope occurring at the onset of anesthesia. Professor Heymans of Ghent presented a paper on the pharmacodynamics of the vasomotor and cardiac action of epinephrine. Professor Burgi of Bern gave a critical study on combinations of drugs, pointing out that a heightened effect is secured only when substances are combined that produce the same physiologic result by different routes. In the section of physical therapy, Professor Bordier of Lyons discussed the treatment of radiodermatitis and its complications. Mr Joly enumerated the precautions to be taken to avoid radiodermatitis. Professor Binet described the physiologic reactions of the organism in hyperthermic treatments. A Dognon and his collaborators gave an account of the use of short waves in biology and in medicine. A comprehensive study was presented by Levaditi, Auclair, P. Haber, Henri de Rothschild, Vaisman and Mlle Schoen on experimental thermotherapy by means of short wave irradiations. They reached the conclusion that the germicidal action is not the most important factor but that the heat increases the defense reactions of the organism, irrespective of the type of pyrotherapy employed.

Vaccination Against Typhus Fever

Two new vaccines against typhus fever have recently been presented to the Academy. Heretofore the only vaccines in use have been the vaccine of Castaneda-Tinsser which protects only against mouse typhus, which is the least pathogenic and the phenicated vaccine of Weigt, prepared from the intestine of lice infected with *Rickettsia* which is not always effective. Professor Nicolle J. Laigret and P. Giroud utilized a greatly attenuated living virus which is capable of conferring immunity on man by the inoculation of very weak but steadily increasing doses with long intervals over a period of three months. Mr Blanc, director of the Pasteur Institute of Casablanca has presented to the Academy in collaboration with Nourv, Balthazard and Barheoud, a new vaccine derived from rats infected with typhus in Casablanca. This virus is a living vaccine, attenuated by cultivation with addition of bile but still pathogenic. It immunizes not only against mouse typhus

but also against ordinary exanthematous typhus. Twenty subjects treated in this manner showed themselves completely refractory to a virus that killed all the animal controls, including a monkey. The vaccinated subjects are not germ carriers, and their blood cannot infect lice that bite them. This vaccination is benign and produces no febrile reaction. This mode of vaccination would doubtless contribute to the eradication of typhus among the native populations of northern Africa.

The National Syndicate of French Surgeons

The Syndicat national des chirurgiens français held a meeting in Paris during the regular session of the Congress of Surgery. The chief subject discussed was "The Assignment of Surgical Services of Cities Solely to Surgeons with Approved Special Training." It will be recalled that the Academy of Medicine went on record as opposed to the creation of a surgical diploma based on special examinations. The syndicate has, however, decided to create a "brevet de chirurgien," or surgeon's certificate, which it will supply itself—first to its own members, and secondly to applicants who meet the following conditions: (1) professors and associate professors of surgery in a faculté de médecine or in an école supérieure de médecine, (2) former hospital interns of a city in which they are appointed on the basis of a competitive examination and who have spent three years in a surgical service, (3) other candidates who have passed a test before a special board of surgeons and who present their publications on surgical questions. The syndicate emphasizes that, in the smaller cities, the emergency services should be available preferably to surgeons with the foregoing qualifications. The law, of course, permits every doctor of medicine to practice surgery with perfect freedom. The syndicate however, hopes to awaken a discrimination in the public mind by increasing the prestige of the surgeon holding its special certificate.

The Crusade Against Narcotics

A decree signed by the president of the republic creates, under the direction of the Sureté générale, a special bureau designed to apprehend illicit dealers in opium, morphine, diacetylmorphine (heroin) and cocaine. The bureau will be directed by Mr Ducloux, with the assistance of Mr Mouganel, who, as police commissioner, has specialized in this field for some time. This new service will centralize all problems concerning narcotics, which heretofore have been distributed among various departments (agriculture, customs, commerce, pharmacy, justice, foreign affairs), which made it comparatively easy for illicit dealers to escape investigation. Henceforth, only a single file on the subject will be kept and that in this bureau, where all the information obtainable will be collected. It may be noted that France is no longer a producer of narcotics that figure in illicit selling, they all come from Germany, Turkey and the Far East. Narcotics do not assume relatively as big a role in France as in many other countries. But France is in line of transit for all these substances and, only recently, two tons of narcotics, destined for exportation were seized at Marseilles. Every instance of seizure of drugs will be reported by the ministry of foreign affairs to the consultative commission on opium of the League of Nations, with a view to facilitate the investigations of the commission.

Foreigners in Hospitals in France

The government is planning to revoke the convention entered into with Italy, Poland, Belgium and Luxemburg concerning reciprocity of treatment for their nationals in French hospitals and their participation in the benefits of social aid and of compensation allowances for the unemployed, the infirm and the aged. The convention was signed in 1920, immediately after the war, when 1,500,000 men had been killed and the

factories in the North destroyed by the Germans. It was necessary then to encourage immigration of workmen. Now the factories have been rebuilt and there are nearly a million unemployed in France. Furthermore the term 'reciprocity' is a misnomer, for there are but few Frenchmen in Poland and in Italy, whereas there are several hundred thousand Italians and Poles in France. The Italians who seek to avoid fascism are extremely numerous along the Mediterranean Coast. The city of Nice expended in 1929, for foreign patients 2,174,407 francs (\$86,000) in 1930 2,427,833 francs (\$97,000) and in 1932, 1,367,616 francs (\$54,000). In Marseilles the number of patients was so large that it was necessary to create a special hospital, which receives an appropriation from the Italian government. These expenditures when paid by the municipalities, make considerable inroads on their budgets. The present trend is to accept patients with acute disorders, confinement cases and patients with injuries but to return to their native country all chronic patients, the infirm and especially the tuberculous for the sanatoriums although the number is being constantly increased are still inadequate for the French patients. Furthermore, the countries bordering on France are following this course in dealing with French chronic patients.

The Sanatorium for Students

Although its construction was provided for by the decree of May 22, 1925 the Sanatorium des étudiants has only recently been opened to patients. There have been many delays owing to lack of funds. The sanatorium is located at St Hilaire du Touvet, in the department of Isère at an altitude of 1,150 meters, well protected on the north by mountains. A beautiful view of Mont Blanc is afforded. There are 180 beds with a separate pavilion of thirty beds for the admission later, of women students. Only students of French universities belonging to the Association nationale are ordinarily admitted. But the directing council has the authority to admit by way of exception, students who are not affiliated with this association pupils from higher institutions of learning not of university rank, and even university professors. The maintenance charge is placed at 40 francs (\$2.40 current exchange) per day the government assuming any deficit that occurs. Unless there are medical reasons requiring isolation, each room accommodates two or three boarding patients. Everything is provided for the comfort of the patient. To a partial extent students will be able to continue their studies here, the sanatorium being provided with study halls, a fine library and lecture courses held by professors from the University of Grenoble near by. All examinations on work done are given at Grenoble.

BERLIN

(From Our Regular Correspondent)

Nov 27, 1933

Criteria for the Interruption of Pregnancy

Recently, changes were made in the law concerning the medical interruption of pregnancy (*THE JOURNAL*, Sept 23, 1933, p 1011). Following the precedent of another *aerztekammer*, or chamber of physicians, the directorate of the Berlin *aerztekammer* has adopted criteria on the subject. To establish the indications for the interruption of pregnancy, special consulting physicians have been appointed, in every municipal district of Berlin, for all the specialties concerned internal medicine, gynecology, surgery, neurology, ophthalmology, otology, cutaneous diseases, urology and orthopedics. These consultants assume toward the directorate of the "chamber of physicians" the obligation of transmitting to the *aerztekammer* the protocol of their deliberations as drawn up with the aid of the attending physician. The consultants are provided with numbered blank forms for this purpose. The fundamental con-

dition for the interruption of pregnancy is reliable evidence that a danger threatens the life and health of the gravida which can be eliminated in no other manner. Interruptions of pregnancy may be undertaken only in the public hospitals and private clinics that have been expressly approved by the chamber of physicians. Decisions based on eugenic considerations must be left to the so called hereditary health courts, for the creation of which provision is made in the new sterilization law (*THE JOURNAL*, Sept 9 1933 p 866). Consulting physicians may render an opinion only in cases coming within the range of their specialty—the gynecologist for example, only in obstetric-gynecologic diseases or severe endocrine disorders including hyperemesis. If it is in any wise possible there should be an examination in common and a joint consultation by the two or more physicians concerned and the result of this consultation should be recorded in the blank form. If such a consultation is impossible (for example in the rural districts) the referring physician must send in detailed observations. The mere statement of a diagnosis such as heart defect, tuberculosis, catarrhal condition of the pulmonary apex, or the like will not constitute a sufficient basis for a decision. After the protocol has been signed the execution of the intervention must if possible be entrusted to a specialist. The special medical consultants have jurisdiction only in their districts, and they are not authorized to undertake the interruption in the cases in which they render an opinion. If the patient refuses to accept the special medical consultant or if she is not satisfied with the opinion of the consulting physicians she can apply only to a public hospital as no private practitioner is permitted in that case to undertake the interruption. Likewise in the hospital, a similar consultation of the specialists concerned must be held and a written protocol in the case be prepared. A consultation on the subject between medical directors and assistants is not permissible nor is a consultation between associated physicians allowed.

The *aerztekammer* gives the following further explanation of the situation. The new regulations will be accepted, by the upright and honorable physician as a matter of course. Physicians who are lacking in backbone will derive courage from them. But we feel it our duty to warn those of our colleagues who may try to protect their abortion plants by alleging that they handle only such abortions as are 'already under way'. Such physicians place themselves outside the pale of reliable and decent colleagues. The medical profession of Berlin does not take the attitude that a spirit of fraternal consideration requires it to enter the lists to protect the honor of these physicians.

It goes without saying that likewise illegal abortions undertaken by nonmedical persons will be punished. The present strict attitude of the courts toward crimes against budding life is revealed moreover, by the fact that recently a man aged 62 received an eight-year penitentiary sentence.

The Status of Venereal Diseases

At the meeting of the German Society for the Combating of Venereal Diseases, Dr Reiter, president of the public health service, stated that according to the 1927 census of venereal patients, Germany has to face annually an accretion of 372,000 venereal patients, 280,700 of whom have gonorrhea. The actual number is much greater, for numerous patients are not covered by the census. Venereal diseases are still the most widespread infectious diseases. In 1927, 7,500 children were born with external syphilitic manifestations, while in many more children the disease did not manifest itself until later. Furthermore, 1,500 children gave evidence of gonorrhea, in many cases associated with blindness. The age groups chiefly affected by venereal disease are 18-25. Divorced persons are the class most affected, next in order are unmarried persons. How

ever, 25.3 per cent of the male patients and 28.2 per cent of the female patients were married.

The cities, particularly the seaports, are the worst hotbeds of venereal disease. In Hamburg for example, the total number of cases annually of gonorrhea in the men and women of the 15-50 age groups is 109.25 per cent of the number of persons belonging to those groups which reveals that not a few are affected two or more times, since a considerable number of men and women remain exempt. In Berlin the corresponding percentage is 88.05.

The financial burden occasioned by venereal diseases amounts in Frankfurt-on-Main to 930 marks (\$140) a year for each person of the total population, which does not include the expenditures resulting from useless pregnancy, miscarriages and stillbirths, and deaths of the new-born. It is evident that Germany as a whole suffers an annual burden of more than \$100,000,000. By the creation of working mergers of the insurance carriers (the Krankenkassen and the like), the communes and the medical profession, to promote prompt thorough treatment, a rapid improvement of conditions might be brought about. Such mergers would be able to operate at an approximate cost of \$15,000,000 annually.

The chairman of the meeting Professor Spiethoff of Jena demanded, in addition to proper treatment the detection and eradication of the sources of infection, compulsory notification and suppression of prostitution. At the same time, early marriage must be promoted, the housing situation must be improved, and the relations between the sexes must be placed on an ethical basis.

Death of Prof. Christian Baeumler

Prof. Christian Baeumler, the Nestor of German clinicians and perhaps the oldest clinician in the world, died in Freiburg-in-Breisgau, at the age of 97. He had been a physician since 1860, having served for a long period at the German Hospital in London and later at the Victoria Hospital. In 1872 he became professor extraordinary at the University of Erlangen and later, ordinarius and director of the Innere Klinik in Freiburg which post he occupied until 1909. His numerous published works deal chiefly with diseases of the lungs and the heart, hydrotherapy and syphilis.

BELGIUM

Oct. 30, 1933

Results of Treatment in the Preventorium

Dr. Van der Smissen surveys statistics bearing on six years of work of the preventorium at Clemskerke during which period 5,886 children passed through the institution receiving an average of 124 days of treatment per child. Forty per cent of this group were children aged 5 to 6 who had not yet attended school. The principal diseases and the number treated were as follows: anemia, 1,420; debility, 2,208; tracheobronchial adenopathy, 898; cervical adenitis, 1,096; and asthma, 264. It may be said of the anemic and the weakly children that they are the classes most neglected in pediatrics; most of them belong to wealthy families. It would have been well to apply the skin reaction to all of them. Radioscopy was not applied as a routine measure. Tracheobronchial adenopathy which is difficult to diagnose requires a careful period of observation. Many cases of infected rhinopharynx simulate and are often taken for tracheobronchial adenopathy. The abdominal cases the number of which ranged around 50 per cent, are children in the period of growth with hepatic insufficiency, fetid breath, constipation and weak appetite. A visit at the seaside puts an end to these disorders in a few days. Asthmatic patients contrary to opinion, improve greatly from a sojourn at the seaside.

In fact of all the diseases that showed betterment at the preventorium asthma held first place.

As to the causes for these excellent results, one may mention (1) fresh air strict discipline assuring a complete air treatment in all weather, outdoor life being possible at the seaside so long as it does not rain, (2) exceptional quality of sea air, it being almost entirely free from bacteria (at the seaside one does not take cold except from an east wind, that is to say, from off the continent), (3) heliotherapy, which is not practicable in Belgium other than at the seaside, (4) the general diet of the group which is a factor in the improvement and (5) sea baths, which have a markedly stimulative effect on the appetite (the contraindications are few but imperative: otitis, eczema, nephritis). Summer is the most favorable season for the application of sea baths in the treatment of peritoneal tuberculosis, rickets, suppurative adenitis and certain anemias. In the other cases, or 90 per cent of the total, winter treatment is preferable.

Convention on Chronic Rheumatism

Under the chairmanship of Van Cauwenberghe and Nobelet the Royal Society of Medicine of Ghent organized recently a convention devoted to the consideration of chronic rheumatism. More than 150 physicians from all parts of Belgium, attended.

Mr. P. Weil, physician to the hospitals of Paris, discussed tuberculous rheumatism, the existence of which appears today unquestionable. After describing the various forms of tuberculous rheumatism (in acute form resembling acute articular rheumatism, and a chronic deforming type, symmetrical and generalized), Weil considered the value of diagnostic tests. He emphasized also the favorable prognosis of this form of tuberculosis.

Van Breemen of Amsterdam, general secretary of the Ligue internationale contre le rhumatisme gave the results of his long experience with chronic rheumatism. He emphasized the importance of cutaneous and vascular disorders presented by rheumatic subjects, and also the changes in hydrogen ion concentration and of the percentage of sugar in the articular fluid so carefully studied by American authors. He called attention to the rheumatism of the menopause in women which is characterized by peculiar clinical symptoms and which, if treatment is begun in time may give encouraging results.

Mr. Brogitter of Berlin, who for more than ten years has devoted himself to this problem gave an anatomopathologic demonstration of chronic forms of rheumatism, and particularly of gout. He illustrated his presentation with microscopic slides.

Mr. Isidore Cunzberg of Antwerp announced the objectives set by the Ligue belge contre le rhumatisme, and the results secured at the rheumatism center of the Brugmann Hospital in Brussels. He gave an outline of his classification of chronic forms of rheumatism based on certain anatomopathologic data.

Trachoma in Kasenga

Addressing the Cercle medical du Katanga (Belgian Congo), Dr. Dixon gave an account of his experiences in the crusade against trachoma in the province of Kasenga. Of 10,920 natives examined a diagnosis of trachoma was reached in 1,099, or 10 per cent. In the region of Kasenga, as elsewhere, trachoma presents frankly a familial distribution: one village may be seriously affected while another remains almost exempt. The percentage of cases of trachoma amounts to 13.6 along the Luapula River, while west of the Kundelungu Mountains it does not exceed 6.1. Cases of ordinary conjunctivitis are likewise more frequent along the river. The highest percentage (21) was observed in the district of Kikungu. Trachoma presents in this region only an average severity.

Of the trachomatous patients examined, pannus and trichiasis are observed in 8.5 per cent of the cases. This rather low figure represents approximately the percentage of patients whose vision is diminished. Unfortunately, a census and a systematic

examination of the blind have not been made, but it appears that trachoma is not responsible for more than 20 per cent of the cases of blindness. About 65 per cent of the trachomatous patients examined were under 15 years of age although the number of adults and of children examined was approximately the same. This fact appears to show that in the members of the black race of this region trachoma may heal and disappear without leaving any traces. Four antitrachoma centers have been created where likewise patients affected with other disorders are treated. More than 150 trachomatous children have been subjected thus far to regular treatment extending over one to three months and consisting simply of daily applications of a 2 per cent solution of silver nitrate. Trachoma has not been cured in many of these children. The treatment is however, appreciated (although rather painful) as is shown by the continued presence of the patients. The cure of ordinary conjunctivitis with silver nitrate by checking the lacrimation must have reduced perceptibly the contagiousness of trachoma in this region.

Seasonal Variations of Diphtheria

At the International Bureau of Public Health Gubler and Nels presented an article on the seasonal variations of diphtheria. It has been found in Belgium as in other countries that there is less diphtheria in summer than in winter. During the year 1931 and 1932, Dr. Nels performed 4084 Schick tests and he secured the figures shown in the adjoining table.

	Totals	Schick Positive	Percentage Positive	Schick Negative	Percentage Negative
Winter	1745	866	49	877	51
Intermediate season	1015	520	51	495	49
Summer	1324	190	14	1134	86
Totals or averages	4084	2076	50	2008	50

It is evident that there is not the least difference in the percentages of Schick positive tests with relation to the season. These results are in opposition to those reported by Lubisz who expressed the view that the variations in the susceptibility of the human organism toward the toxin were the cause of the seasonal variations in the incidence of diphtheria and that these variations of susceptibility effect a diminution or an increase of the percentage of antitoxin in the blood of subjects dependent on the period of the year.

Marriages

VIRGINIUS BITZLER HIRST New York, to Miss Harriet Angelina Ellison at Charlotte N. C., Dec. 27, 1933.

EDWARD J. WACNER New York, to Miss Frances Mae Daniels of Fort Edward, N. Y., Dec. 24, 1933.

HOMER LORLANZO HILES, Conneaut Ohio to Miss Miriam R. MacKenzie of Oil City, Pa., Dec. 20, 1933.

MARTIN J. PATRICK to Miss Caroline Bobbin, both of Shenandoah, Pa., at Detroit, Aug. 26, 1933.

DOUGLAS HEATH NISBET, Charlotte N. C., to Mrs. Pauline Hood Bowers at Kinston Dec. 16, 1933.

WILL MADDUX McCLARIN to Miss Emma Nan Harris both of Louisville, Ky., Dec. 16, 1933.

ROBERT J. HOLZBERGER to Miss Catherine Speer, both of Great Falls, Mont., Nov. 20, 1933.

MORRIS HARWITZ to Miss Fannie Y. Shevitz, both of Wilmington, Del., Dec. 24, 1933.

BERNARD I. COMROE, Philadelphia to Miss Grace Miller of Allentown, N. J., January 1.

BERNARD DAVID ROSENAK to Miss Fannie H. Kiser, both of Indianapolis, Dec. 14, 1933.

AUGUSTUS G. POHLMAN to Mrs. Helen B. Shartie both of Omaha, recently.

LOUIS O. WOOTTEN, Cordele, Ga. to Miss Kathryn Royal Nov. 29, 1933.

Deaths

Linsly Rudd Williams of New York, Columbia University College of Physicians and Surgeons New York 1899, director of the New York Academy of Medicine, managing director of the National Tuberculosis Association 1922-1928, past president of the New York Tuberculosis and Health Association, deputy commissioner of health of New York state, 1914-1917, member of the American Public Health Association, director of the Milbank Memorial Fund, member of the board of managers of the New York Association for Improving Conditions of the Poor, trustee of Columbia University, instructor in histology, 1902-1904, assistant in medicine 1904-1914, and chief of the medical clinic, 1906-1911 at his alma mater, served during the World War following which he served the Rockefeller Foundation as director of tuberculosis work in France, aged 58, died January 8, at the Rockefeller Institute for Medical Research.

Alexis Victor Moschcowitz of New York, College of Physicians and Surgeons Medical Department of Columbia College New York 1891, formerly professor of clinical surgery at his alma mater, member of the American Surgical Association and the American Association for Thoracic Surgery, fellow of the American College of Surgeons, served during the World War, on the staffs of the Mount Sinai Beth David and Bronx Maternity hospitals New York, the United Israel Zion and the Brownsville and East New York hospitals Brooklyn, aged 68, died Dec. 21, 1933, of coronary thrombosis.

John Stewart, Halifax N. S. Canada University of Edinburgh Faculty of Medicine Edinburgh Scotland 1877, formerly professor of surgery and dean Dalhousie University Faculty of Medicine, served overseas during the World War, past president of the Provincial Medical Board of Nova Scotia and the Medical Council of Canada, fellow of the American College of Surgeons, at one time on the staff of the Halifax Infirmary, aged 85, died Dec. 26, 1933.

George John Muellerschoen Philadelphia, Jefferson Medical College of Philadelphia 1904, member of the Medical Society of the State of Pennsylvania, the Medical Society of New Jersey and the American Urological Association, aged 50, on the staff of the Jefferson Medical College Hospital where he died Dec. 18, 1933, of complications, following a mastoid operation.

Charles Austin Willis, Waltham, Mass. Harvard University Medical School Boston 1897, member of the Massachusetts Medical Society, at one time medical inspector of the board of health of Waltham and member of the state board of health, formerly on the staffs of the Waltham Baby Hospital and the Waltham Hospital, aged 65, died, Dec. 10, 1933.

Julian Turnbull McClymonds of Berkeley, Calif., University of Michigan Medical School, Ann Arbor, 1894, member of the Kentucky State Medical Association, fellow of the American College of Physicians, served during the World War, formerly on the staff of St. Joseph's Hospital, Lexington, Ky., aged 63, died Dec. 4, 1933, of heart disease.

Henry F. Page of Philadelphia, University of Pennsylvania School of Medicine Philadelphia 1893, associate professor of medicine, University of Pennsylvania Graduate School of Medicine, formerly clinical professor of medicine, Woman's Medical College of Pennsylvania, medical superintendent of the Lankenau Hospital, aged 63, died, Dec. 21, 1933.

Wyman Dean Jacobs, East Poestenkill, N. Y. University of the City of New York Medical Department 1891, member of the Medical Society of the State of New York, for many years county jail physician, aged 66, died, Nov. 16, 1933, of coronary thrombosis and arteriosclerosis.

David Earl Yantis of Urbana, Ill., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1902, past president of the Champaign County Medical Society, aged 63, died, Dec. 11, 1933, in the Carle Memorial Hospital, of diabetes mellitus.

Purdy H. Sturges, Plainfield N. J. College of Physicians and Surgeons Medical Department of Columbia College New York 1887, formerly on the staff of the Methodist Episcopal Hospital Brooklyn, aged 69, died Dec. 8, 1933, of chronic myocarditis and coronary thrombosis.

William Calvin Steele Mount Olive N. C. University of Maryland School of Medicine Baltimore 1891, member of

the Medical Society of the State of North Carolina president of the Wayne County Medical Society, aged 66 died, Nov 14 1933, of cerebral hemorrhage

Grover Cleveland Webb, Russellville, Ark., University of Tennessee College of Medicine, Memphis 1917 member of the Arkansas Medical Society served during the World War aged 40, on the staff of St Mary's Hospital, where he died Nov 27, 1933

Benjamin Oran Works, Brownsville Texas University of Texas School of Medicine Galveston 1906 past president and secretary of the Cameron County Medical Society served during the World War, aged 51 died, Dec 16, 1933 of heart disease

Bernhardt Jacob, Detroit Detroit College of Medicine 1891 formerly superintendent of the Detroit House of Correction, aged 63 died Dec 1, 1933 in the Grace Hospital of diabetic gangrene of the left leg and pulmonary embolus

Robert Fuller Hogsett, Albuquerque N. M. Jefferson Medical College of Philadelphia 1927 member of the New Mexico Medical Society, aged 30 died, Nov 26 1933 in St Joseph's Hospital of skull fracture the result of a fall

Henry Elijah Somers, Newport Vt. University of Vermont College of Medicine Burlington 1903 member of the Vermont State Medical Society served during the World War, aged 52, died, Nov 24 1933 of angina pectoris

George B. Cowell, Bridgeport Conn. College of Physicians and Surgeons, Medical Department of Columbia College New York, 1888 aged 67 on the staff of the Bridgeport Hospital, where he died Dec 11 1933 of heart disease

George Washington Graves, Brownfield Texas Memphis (Tenn.) Hospital Medical College 1902 president of the Dawson Lynn-Terry-Graves Counties Medical Society, aged 61, died, Nov 18 1933 of coronary thrombosis

Harry Lynn Beers, Youngstown, Ohio University of Michigan Medical School Ann Arbor 1909 member of the Ohio State Medical Association aged 60 died Dec 5 1933 of coronary thrombosis and acute nephritis

Donna Ann Waldran, Baltimore, Woman's Medical College of Baltimore 1890 Southern Homeopathic Medical College Baltimore, 1893, aged 74 died Dec 11, 1933, in a local hospital, of chronic nephritis and uremia

Walter Brown Willey, Jr., Everett, Mass. Tufts College Medical School, Boston, 1917, member of the Massachusetts Medical Society served during the World War aged 41 died suddenly, Dec 7, 1933, of heart disease

James Arthur Connor, Waverly Kan. College of Physicians and Surgeons, Medical Department Kansas City University, 1903, aged 56 died, Oct 30 1933 in St Francis Hospital, Topeka, of diabetes mellitus

James L. Cochran, Connellsville Pa., Western Pennsylvania Medical College, Pittsburgh, 1895 on the staff of the Connellsville State Hospital aged 63 died suddenly Nov 22, 1933 of coronary thrombosis

Frank Holyoke, Holyoke Mass. Harvard University Medical School, Boston 1883, on the staff of the Holyoke Hospital, aged 78, died, Dec 5, 1933 of cerebral thrombosis and arteriosclerosis

John Ignatius Urban, Chicago Jenner Medical College Chicago 1917 on the staff of the Norwegian-American Hospital aged 40 was found dead, Dec 1, 1933 of an overdose of sleeping potion

Carlos Brown Meadows, Valdosta Ga. University of Georgia Medical Department Augusta 1899 member of the Medical Association of Georgia, aged 61 died Dec 8 1933 of heart disease

Arthur David Henshey, Cleveland Georgetown University School of Medicine Washington, D. C., 1933, aged 26 intern at St Alexis Hospital, where he died, Dec 10 1933, of scarlet fever

David Graham, Duluth, Minn. Detroit College of Medicine 1893, formerly member of the state legislature physician and owner of the Duluth Hospital aged 74, died Nov 4 1933 of endocarditis

Robert Wallace, Louisville Ky. L.R.C.P. Edinburgh, and L.F.S. Glasgow 1880 and University of Glasgow Medical Faculty 1885 aged 80 died, Dec 1 1933 of parenchymatous nephritis

James Henry McSloy, Portland Ore. Rush Medical College Chicago, 1886 member of the Oregon State Medical Society aged 69 died Nov 16 1933 of uremia nephritis and hypertension

James William Wheeler, Coquille, Ore., University of Tennessee College of Medicine, Memphis, 1913, served during the World War, aged 51, died, Nov 13, 1933, of cerebral hemorrhage

Charles Robert Brown, Marion, Ind., Hospital College of Medicine Louisville, Ky., 1907, on the staff of the Grant County Hospital, aged 54, died, Dec 1, 1933, of cerebral hemorrhage

Alfred Robinson, Columbus, Ohio, Miami Medical College Cincinnati 1879 formerly sergeant at-arms of the House of Representatives, aged 82, died, Nov 23, 1933, of arteriosclerosis

James E. Trexler, Kansas City, Mo., University of Pennsylvania School of Medicine, Philadelphia, 1898, aged 59 died, Nov 23 1933, in Neosho, of injuries received in an automobile accident

George Dewey Gertson, Grand Forks, N. D., Northwestern University Medical School, Chicago, 1927, aged 35 died, Dec 1 1933, in Tucson, Ariz., of tuberculosis of the spine

Valentine Charles Lucas, Lakewood, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1888, aged 65 died Nov 23 1933

Cole Carroll, Apopka, Fla. Atlanta (Ga.) School of Medicine 1912 member of the Florida Medical Association, aged 48 died, Nov 9, 1933, of acute dilatation of the heart.

Otho C. Jackson, Brady Texas Dallas Medical College, 1903 member of the State Medical Association of Texas, aged 65 died, Nov 30, 1933, of coronary occlusion

Wilbur F. Clippinger, Evansville, Ind., Medical College of Ohio Cincinnati, 1888, aged 70, died, Dec 10, 1933, in the Protestant Deaconess Hospital, of arteriosclerosis

Frank Yeomans Neer, Paterson, N. J. Columbia University College of Physicians and Surgeons New York, 1905, aged 51, died, Nov 30, 1933, of heart disease

Edmond D. Barron, Pattison Miss., Louisville (Ky.) Medical College, 1888, aged 69, died Nov 29, 1933, of carcinoma of the stomach and chronic myocarditis

Frank Cecil Vause, Stewart Manor N. Y. Long Island College Hospital, Brooklyn, 1910, aged 53, died, Nov 14, 1933 in a hospital at Brooklyn, of pneumonia

Bruno Louis Sulzbacher, Kansas City Mo., University Medical College of Kansas City, 1895 aged 59, died, Nov 14, 1933 of a skull fracture received in a fall

Charles Victor L. Harbaugh, Lapaz, Ind., University of Maryland School of Medicine, Baltimore, 1889, aged 72, died, Dec 9, 1933, of pneumonia

Adam Rankin Johnson, Buffalo, Medico Chirurgical College of Philadelphia 1900, aged 64, died, Dec 5, 1933, of acute coronary occlusion

Charles E. Wright, Gurdon, Ark., Memphis (Tenn.) Hospital Medical College 1903, aged 62, died, Nov 30, 1933, of cerebral hemorrhage

Kenneth Keith MacAlpine, New York New York University Medical College 1896, aged 62, died, Dec 9, 1933, of coronary thrombosis

James Joseph Cole, Chicago, Northwestern University Medical School, Chicago, 1903, aged 55 died, Dec 15, 1933, of endocarditis

V. Verne Vance, Peru Neb., University of Nebraska College of Medicine, Omaha, 1903, aged 55, died, Nov 25, 1933, of pneumonia

Oscar P. Voigt, Gillett, Wis. Starling Medical College Columbus 1895, aged 61, died, Nov 19, 1933 of a self-inflicted bullet wound

William Berry, Omaha Starling Medical College, Columbus 1888 aged 71, died suddenly, Dec 3, 1933 of heart disease

Lynn Cecil Olmstead, Chicago Bennett Medical College Chicago 1912, aged 43, died, Dec 16, 1933 of cerebral embolism

Salem B. Town, Greencastle Ind., Chicago Medical College 1868, aged 86 died suddenly, Dec 5, 1933, of heart disease

Anthony Balcerzak, Chicago Illinois Medical College, Chicago 1909 aged 61 died suddenly Dec 2, 1933

S. Annie Yates, Cincinnati (licensed, Ohio 1896), aged 83 died, Dec 3, 1933, of pneumonia

Correspondence

YAWS AND SYPHILIS

To the Editor—An article appeared in the *Tropical Diseases Bulletin* for November, 1933, entitled "Yaws and Syphilis Two Diseases or One?" which, in all fairness should have some editorial notice.

Physicians in Great Britain have been fighting among themselves for a couple of centuries whether yaws and syphilis are or are not the same disease. A group of Americans principally U. S. naval medical officers, have for years sustained the unity idea but another group of writers is quoted extensively in Blacklock's article. Blacklock proves the proposition that yaws and syphilis are the same thing, but quotes the army writers.

As one of many Americans who have sustained unity, I have myself published the following papers on this subject during the past twenty years:

Butler C. S. The Application of Wassermann's Reaction to the Solution of the Etiology of Tropical Ulcerations (from the laboratory and native clinic of the United States Naval Hospital, Panama). I read before the Far Eastern Association of Tropical Medicine Third Biennial Congress Saigon in November 1913 and published in the Association's proceedings for that year. *U. S. Na. M. Bull.* 51, 1915.

Butler C. S. Some Facts and Some Fancies Regarding the Unity of Yaws and Syphilis. *U. S. Na. M. Bull.* 5, 561, 1911.

Butler C. S. and Petersen F. La treponematose et l'hygiene publique. *Presse med.* July 27, 1927, p. 941.

Butler C. S. and Petersen L. Treponematosis as Seen in Rural Population of Haiti. *Am. J. Syph.* 12, 251 (April) 1927; also in *J. Lab. & Clin. Med.* 12, 670 (April) 1927.

Butler C. S. Primitive Syphilis. *U. S. Na. M. Bull.* 20, 553 (July) 1928.

Butler C. S. Presidential Address (American Society of Tropical Medicine). *Am. J. Trop. Med.* 8, 363 (Sept.) 1929.

Butler C. S. Relation of Syphilis and Yaws. *Ann. Int. Med.* 7, 175 (Aug.) 1929.

Butler C. S. Diagnosis and Treatment of Yaws. *Internat. Clin.* 2, 1 (June) 1930.

Controversies on yaws and syphilis and origin of syphilis published in the *Lancet* between April and July 1931 reprinted in *U. S. Na. M. Bull.* October 1931.

Finish of Controversies on Yaws and Syphilis. *U. S. Na. M. Bull.* January 1932.

Butler C. S. Hero Worship and the Propagation of Illacies. *Ann. Int. Med.* February 1932.

The Trouble with Yaws editorial. *Am. J. Clin. Path.* May 1932.

Butler C. S. De la treponematose en marge des rapports du yawn et de la syphilis. *Ann. de dermat. et syph.* 1188 (Nov.) 1931.

The matter treated here is far from academic. Thousands of pages have been wasted and gallons of ink spilled, to say nothing of years of retardation of medical thought and centuries of fallacious teaching.

I hope that you will find it possible to give some recognition to American investigators who have done much good work in connection with this subject which the English authorities are unwilling to acknowledge.

C. S. BUTLER, M.D. New York

INTERPLEURAL SINUS OR MEDIASTINAL HERNIA?

To the Editor—In the interesting and rare case reported by Drs. C. R. Smith and H. S. Willis in *THE JOURNAL*, Oct. 14, 1933, page 1224, there evidently was no communication between the two pleural cavities, contrary to the conclusions of the authors. Instead there was a mediastinal hernia of the right lung invading the left hemithorax to an unusual extent. The pneumothorax needle repeatedly inserted into the left side of the chest was really in the right pleural cavity each time. The roentgenograms submitted by the authors show the mediastinal hernia of the right lung—it nearly reaches the left axilla. The roentgen examinations following the injection of air into the left side of the chest showed no collapse of the left lung, but the right lung was entirely separated from the chest wall. The manometric readings made with two needles, one in the

left side and one in the right side of the chest, show that the two needles were in one and the same pleural cavity. Post mortem "no channel of communication could be found" between the two pleural sacs although pains were taken to demonstrate such a sinus.

Dersheid and Toussaint (Pneumothorax artificiel droit par implantation d'une aiguille dans l'aisselle gauche, *Arch. med. Chir. de l'app. respir.* 7, 68, 1932) reported a similar case. A pneumothorax needle inserted into the left axilla produced a collapse of the right lung due to invasion of the left hemithorax by the right lung.

LEONARDO KOROL, M.D., Lincoln, Neb.

HAZARDS OF DRY CLEANING

To the Editor—I have just read the interesting editorial in *THE JOURNAL*, Dec. 16, 1933, on the hazards of dry cleaning.

My attention was called to the statement in the last part of the third paragraph on page 1970 to the effect that "the purchase of gasoline at a filling station may also involve a hazard other than fire—that of tetra ethyl lead poisoning."

Based on a study carried on by the Public Health Service, regulations for the protection of the public were prepared by a committee of scientists appointed by myself with Dr. W. H. Howell as chairman. You are no doubt well acquainted with this committee and its work. I would, however, call your attention to Bulletin 163 from the Public Health Service, The Use of Tetra-Ethyl Lead Gasoline in Its Relation to Public Health which gives these regulations. You will note that the committee recommends, among other things, that the gasoline containing tetra ethyl lead be colored and that it be used as a motor fuel only. The color was added to prevent the use of this gasoline as a cleaning agent.

It is our belief from investigation and from available data that these regulations satisfactorily protect the public from any possible additional hazard in the use of ethyl gasoline.

H. S. CLARK, M.D. Washington, D. C.
Surgeon General U. S. Public Health Service

INJECTIONS OF PROCAINE FOR SPRAINS AND DISLOCATIONS

To the Editor—The Paris correspondent under date of September 20 (*THE JOURNAL*, November 4, p. 1492) states that the medical profession is indebted to Professor Leriche of Strasbourg for a method of treatment of sprains and mild luxations, which consists in injecting a cubic centimeter of a solution of procaine hydrochloride (1:1,000) at the level of the painful areas. A person with a sprain thus treated can walk immediately after the injection.

A person so treated can walk immediately, but should he do so? I think that he should not, unless the sprained part is efficiently splinted (as with adhesive strapping). If by medication one stops pain and muscle spasm and then permits strain to be thrown on the injured tissues those tissues have not a good chance to heal by first intention. Prolonged convalescence and impaired function are likely to be the result.

The correspondent continues: Schulmann and Benassy have applied this method to persons with rheumatic pains with complete success. Even in cases of chronic arthritis the injection of procaine at the insertions of the ligaments and the articular tendons brought about quickly not only relief from the pain but also restoration of the movements.

If the aim in treatment of arthritic patients is anything more than ephemeral relief from pain the treatment of these patients by the injection of a local anesthetic is just as illogical as the proposed treatment of sprains.

No doubt the Paris correspondent knows whereof he speaks when he states that the medical profession is indebted for this form of therapy. Would it not be well to inquire into the facts on which this indebtedness is based before subjecting patients to this form of treatment?

RALPH R. FITCH, M.D., Rochester, N. Y.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF VINCENT'S ANGINA

To the Editor—Kindly give me information as to further advice and treatment in the following case. A woman aged 45 yrs had a Vincent spirillum infection verified by microscope of the gums and mouth for about a year. Sodium perborate (a teaspoonful in a third of a glass of water) was used as a wash every hour. An injection of neoarsphenamine was followed by a very violent reaction with swelling of the face and lips dyspnea fever a blotchy eruption on the face and body burning of the mouth nausea weakness and indisposition for several days. The teeth were scaled and cleaned. Crowns and bridgework were removed. The patient discontinued brushing the teeth applied an antiseptic mouth wash and omitted fruit juices for a while in the hope that maybe the food was too acid. This was without effect. Tartroquinomine was used locally and intramuscularly, two days later there were pain redness infiltration over the buttocks about the size of a hen's egg fever and increased soreness of the gums. A week later I administered another injection of potassium bismuth tartrate in dextrose solution both being 0.1 Gm with an identical reaction soreness redness of the skin over the buttocks infiltration fever, weakness nausea and indisposition with increase in soreness and redness of the former injection area. I bathed the buttocks first with rubbing alcohol and sterilized the syringe and needle using a 2 inch needle and depositing the bismuth deep in the gluteus muscle. Is it possible that this was an allergy to bismuth, as it must have been to the neoarsphenamine also? There is no mention in the literature of bismuth preparations resulting in such reactions though it is said that they may cause pain but to last with infiltration and redness in the skin for ten days is certainly unusual. The patient has a nasal allergy of seven years standing and I have thought that perhaps these injections acted as a foreign protein exciting the reactions. What treatment would you advise for the infiltration, soreness and redness? If you can suggest anything different for the treatment which must be mild as the mouth gums and throat are very sensitive to strong medication I would greatly appreciate it. The condition has been of long standing, while energetic medication seemingly has been of no avail. Please omit name.

M. D. Oklahoma

ANSWER—It is extremely hazardous to give advice in such a case without immediate examination of the oral lesions and of the smears. Several general principles must be considered:

1. The lesion must present the characteristics of Vincent's infection, hyperemia and passive congestion of the mucous membrane at the base, a gray to yellow-gray pseudomembrane which when removed, reveals a bleeding surface pain on palpation, a foul, putrescent odor and a predilection for the spaces between the teeth and destruction of the interdental papillae.
2. The smear must show a predominance almost to the point of pure culture of the spirillum and the fusiform bacilli. These organisms are normally present in the mouth in small numbers. There is evidence that other organisms must also be present for the characteristic lesion (Smith, D. T. Oral Spirochetes and Related Organisms in Fusio-Spirochetal Disease Baltimore: Williams and Wilkins Company 1932).
3. Systemic disorders must be ruled out: scurvy, diabetes mellitus which often in patients of this age gives rise to swelling redness soreness and often suppuration of the gingival mucous membrane with alveolar bone destruction, poisoning, as from lead and bismuth oral syphilitic manifestations and others.

In this instance, if the lesion is indisputably Vincent's infection, one may advise discontinuance of arsphenamine and bismuth and attack the lesions locally with frequent topical applications of sodium perborate in hydrogen dioxide packing the paste between the teeth and into the pockets for from seven to ten minutes every three hours followed by irrigation with hydrogen dioxide washed forcibly in the interstices between the teeth with a small pointed syringe and used as a mouth wash. A mild laxative may be used. A soft sustaining diet should be advised and extreme caution observed against the spread of the infection by towels, wash cloths dishes and personal contact to avoid infecting other members of the household. Most cases of Vincent's infection will respond to this treatment if rigidly carried out.

Vigorous local treatment is the most efficient, but in order to have it carried out with sufficient aggressiveness it is often necessary to hospitalize the patient.

The reaction to bismuth compounds is not uncommon and should not be compared to an allergic reaction. It should also be noted that the administering of arsphenamine in syphilis is quite often followed by acute reactions in the mouth and gums.

An interesting article appeared in the September issue of the *Dental Cosmos* and one by L. J. Belding and P. H. Belding on evaluation of the various reagents used in the treatment of the spirochetoses in the September issue of the *Journal of the American Dental Association*.

SYNOVITIS AND ARTHRITIS

To the Editor—What is the clinical and pathologic difference between synovitis and traumatic arthritis? Please omit name. M. D. Indiana

ANSWER—Technically speaking, one cannot have synovitis without arthritis. One may have arthritis without synovitis. Synovitis is a symptom, like a cough or fever, and by many is considered not a complete diagnosis. Inflammation of any part of the joint structure is called arthritis. An injury to the internal semilunar cartilage may produce traumatic synovitis and a true arthritis. A somewhat analogous situation may occur in the big toe joint and in the subastragalar and other joints. Osteochondritis dissecans and osteochondromatosis may produce traumatic arthritis.

The etiology of synovitis includes infection, trauma, allergy, metabolic disturbances, neurologic conditions, exposures to extremes of cold and moisture, poisons and drugs. The pathology of synovitis includes hyperemia and swelling of the synovial membrane, increased synovial fluid and later pathologic changes in the synovia, including atrophy, hypertrophy, degeneration and destruction.

The symptoms include pain, swelling, tenderness, limitation of motion and local increase in temperature. Physical examination reveals pain (except in the neuropathic joint), swelling, obliteration

Differential Diagnosis

	Clinical	Pathologic
Synovitis	Pain Swelling Heat Redness Free fluid	Hypertrophy of synovia Round cell infiltration Giant cells Pannus formation
Traumatic arthritis	Pain Swelling heat redness or free fluid may or may not be present	Cartilage erosion—later Osteochondritis dissecans Osteochondromatosis Loose bodies Osteophytes

tion of the normal bony landmarks, limitation of movement, muscle spasm, increased local temperature and atrophy of the local musculature. The synovial fluid is examined for its physical properties, for blood for a mixture of blood and synovial fluid, and for pus or bacteria.

The roentgen observations in synovitis are usually negative except in cases in which thickening is demonstrable. The joint space may appear hazy, from the presence of fluid exudate or thickening of the synovial membrane.

In a discussion on traumatic synovitis, Brickner stated that the effusion in joint sprain is not clear serum but is bloody. Often in traumatic synovitis, especially that due to external violence, the distention is caused by pure blood. Such a hemarthrosis is not distinguishable except by aspiration from a hyarthrosis. In acute traumatic synovitis there must be a tear of the synovial membrane and some injury to ligaments, bone or cartilage. A cartilage fracture, such as occurs on a femoral condyle which is not demonstrable roentgenographically, may be the cause of chronic traumatic synovitis with persistent or recurrent effusion.

Hemorrhagic synovitis is characterized by an injury, following which there is an increase in size of the joint with obliteration of the normal bony landmarks. Aspiration of the joint reveals a bloody fluid.

Leriche described a condition of traumatic vasomotor synovitis. He and Policard believe that many traumas are so comparatively insignificant that they leave no visible signs yet may be followed by serious vasomotor disturbances in the fibrous tissues.

Traumatic arthritis is that type in which it seems plausible to attribute the pathologic changes and therefore the symptoms and roentgen observations to a definite trauma. Trauma may be due to the occupation of the patient when there is strain

on the joint, as in the hands of laborers. A static abnormality may be the cause. The trauma may be due to indirect violence, such as the injury to a shoulder caused by a fall on the outstretched hand which may produce a Colles fracture. Trauma may be one severe one or multiple minimal ones.

Putti believes that, regardless of what the primary or secondary cause of osteo arthritis may be there always enters into the pathogenesis the factor of trauma—not the direct type which produces fracture but that of the persistent chronic type of moderate degree of intensity which occurs under various circumstances. Bone and joint structures make similar responses to unlike factors, such as irritation, traumatic or infectious.

If trauma itself can cause arthritis a classic example is fracture of the os calcis producing subastragalar arthritis. Another example is arthritis which occurs in the shoulder following a Colles fracture.

Hench states that because of their particular function joints must take in addition more physical jolts than any other part of the body functioning with and in spite of an enormous amount of physical trauma which up to a certain degree constitutes physiologic trauma. Beyond this point it constitutes potentially pathologic trauma and may produce chronic arthritis. Hench believes that obesity is one of the important causes of hypertrophic arthritis the weight-bearing joints being constantly subjected to trauma.

APLASTIC ANEMIA WITH PURPURA

To the Editor—A man aged 25 was in excellent physical condition June 9, 1933. His past history and family history were uneventful. On that date following a minor wound of the leg, he was given 100 units of antitetanic serum (age and manufacturer of serum unknown). The next day he developed several areas of water blisters over the shoulders at first thought by his physician to be urticaria and later diagnosed as shingles. These seemed to break down and today there are noteworthy scars at these points. From the date of the serum injection he has gradually but steadily lost ground. There has been a good appetite and a feeling of well being, but he has tired easily and has dyspnea on exertion and he noted a marked tendency to bleed easily. He was first seen by me August 18. There has been no other medical treatment since June 9. He presented marked pallor but no icterus, no weight loss and a few petechiae here and there. The general examination was negative save for a soft systolic murmur at the base of the heart. The urine was normal. Blood examination revealed red blood cells 1,175,000, hemoglobin 35 per cent (Sahli), white blood cells 3,500 (40 per cent polymorphonuclears, 60 per cent lymphocytes). The red cells were only slightly changed in size and shape and there were no embryonic forms or any macrocytes; platelets were 90,000, the bilirubin figure normal, the bleeding time sixteen minutes and the coagulation time eight minutes. A diagnosis was made of an aplastic anemia accompanied by a symptomatic purpura. Three transfusions were given at intervals of forty-eight hours of 500 cc of blood by the citrate method. Three different donors were used, none were grouped but all were cross matched with the recipient. No reaction followed the first two and the red blood cells numbered 2,000,000 and the hemoglobin 47 per cent. Twelve hours after the third transfusion there was a severe reaction of chills and fever. He has now had nine days of this reaction, the temperature being from 99 to 102 F. There is a marked and painful swelling of the right epididymis (there is no history of a gonorrheal infection and the prostate is normal); there has been much suprapubic pain and frequent urination and a very marked hematuria is present. The gums bleed easily and there is only a slight blood reaction in the stool. The spleen is not palpable. Blood examination at this date gives essentially the same results as at the first examination; the clot retracts well and the bleeding and coagulation times are about six and eight minutes. The blood culture is negative for any organisms. The volume index today is 0.82, platelets 100,000. Is this an aplastic anemia and a symptomatic purpura or an essential purpura and secondary anemia? 2. What possibility is there that this whole affair has followed and been caused by the serum? Can you refer me to cases in the literature of serum injections causing such a condition?

P. R. BILLINGSLEY, M.D. Sioux Falls, S. D.

ANSWER—1. Based on the history and examination is given the diagnosis of aplastic anemia with symptomatic purpura seems most applicable to the condition described. In the study of blood dyscrasias, including the severer anemias, leukemias and purpuras, many cases conform with fair accuracy to the typical forms, which have been given disease names based on certain distinctive clinical features, but still other cases present variations from the typical forms, so that question is raised as to whether they belong in one or another disease category. This is true of some atypical cases of aplastic anemia with purpura and hemorrhagic purpuras.

2. It is extremely unlikely that the serum injection was a causative factor in the production of the anemia. It is stated (presumably the patient's statement) that he was in good physical condition, June 9. But a few weeks later at the time when he is said still to have had a "good appetite and a feeling of well being" he already tired easily, was dyspneic on exertion and bled easily. The anemic disease may therefore have already begun to develop either before June 9 or subsequently, so far as was ascertainable from the patient. The occurrence of the minor wound, for which antitetanic serum was

given was coincidental. The herpes or "shingles" that followed the injection of serum may have been due to the serum. Neuritis, sometimes with herpes, has been observed following other serum injections, such as that of antidiphtheric serum.

CHOLESTEROL IN DIET AND SCLEROSIS

To the Editor—In myocardiosis and coronary sclerosis is a diet containing a minimum of cholesterol be beneficial in retarding the advance of sclerosis? Can you suggest to me a dietary containing a minimum of cholesterol? Would a diet free of cholesterol be depriving the body of a necessary dietary constituent?

CHARLES E. IUKENS, M.D. Albuquerque, N. M.

ANSWER—There is no good reason for assuming that a diet containing a minimum of cholesterol would have any influence in retarding the advance of degenerative changes in the arteries or heart muscle. Rabbits fed on a high cholesterol diet have been reported to show changes in the arteries but similar changes may occur in rabbits under other abnormal experimental conditions. There is no convincing clinical evidence that a high fat diet in man has any effect on the arteries. Races such as the Eskimos, living on a diet with a high ratio of fat and protein do not show an increased incidence of arterial changes.

A dietary containing a minimum of cholesterol would eliminate all fats including butter and cream and fat meats, egg yolk, liver, kidney, brains and other valuable and necessary foods. There is some reason for assuming that the body can synthesize cholesterol if withheld from the diet. The blood cholesterol values fluctuate even during fasting and more than normal amounts of cholesterol administered in the food have no significant effect on the blood cholesterol values.

Cholesterol probably performs an important function in the body mechanism. The amount of cholesterol in the blood decreases during infection and returns to normal in convalescence. It is increased in pregnancy and returns to normal after delivery. Cholesterol inhibits hemolysis and is decreased in the blood of pernicious anemia and in other anemias. The cholesterol in the blood is increased in certain pathologic conditions, as obstructive jaundice, diabetes and lipoid nephrosis.

Cholesterol is closely related to vitamins D and A. Ergosterol found in association with cholesterol produces vitamin D when acted on by certain ultraviolet rays. There is every reason for thinking that a diet containing cholesterol in less than the normal values would be harmful. Until a great deal more knowledge has been acquired than is available at present, one should be cautious in interfering with the normal mechanism of the body.

BRONCHITIS AFTER EXPOSURE TO HYDROCHLORIC ACID FUMES

To the Editor—A case of chronic bronchitis was seen recently with a history of six months duration. The patient declares that for the past four years he has been exposed to the fumes of muriatic acid which he used in cleansing metal water meters. During this period he was entirely free from symptoms. It is the patient's impression that his bronchitis is due to irritation from the hydrochloric acid fumes. In view of his freedom from symptoms for almost four years is it probable or even possible that this is true? It should be here stated that no change in working conditions occurred recently to account for greater concentration of the fumes. Please omit name.

M. D. Oklahoma

ANSWER—A marked divergence of opinion has developed with respect to the probability of prolonged disease states after exposure to substances such as chlorine, hydrochloric acid or sulphur dioxide. Investigators of conditions consequent to chemical war gas exposure have long emphasized that irritant gases and vapors produce only acute conditions (possibly with sequelae) in the lungs promptly followed by complete recovery if the initial action is survived. On the other hand industrial hygienists who have observed men working for long periods (eight hours a day) for months or years are disposed to believe that, in some instances, chronic states may arise from such agents as chlorine or hydrochloric acid. At least these hygienists point out the occurrence of chronic bronchitis, inflammation of the upper respiratory tract and rarely paroxysmal asthma. In the case mentioned in the query it does not appear probable that four years of exposure could be endured without involvement and that then, in the absence of any known increase in concentration, a noteworthy bronchitis would be produced. Such a set of circumstances is unlikely. Reference should be made to the chapter on chlorine and hydrochloric acid in Dr. Hamilton's book, *Industrial Poisons in the United States*, New York, Macmillan Company, 1929, and to a similar discussion by Henderson and Haggard in *Noxious Gases*, New York, Chemical Catalog Company, Inc., 1927.

HYPOTHYROIDISM

To the Editor—A boy aged 10 years is but 42½ inches (107 cm) in height and weighs 64 pounds (29 kg). He appears to be obese and has a protruding abdomen. The tissues of the extremities are of myxedematous character. His skin is pale and moderately moist and his hair is somewhat dry. There are large pads of fat over the pectoral regions, shoulders and across the upper dorsal area. His 6 year molars are present as well as the two upper incisors. The lymph glands and the thyroid are not palpable. No upper subcutaneous ducts are made out. The head is large, the eyes are wide set but there is no enlargement of the lips or tongue. His temperature was 98.1, his pulse 60 and regular and respiration 13. A basal metabolism test yielded a reading of 17 per cent. His intelligence quotient is 90 per cent. Flat plates of his wrists showed ossification of the humeri and carpal bones as well as the lower epiphyses of the radius giving an osseous age of about 2 years. His mother states that lack of growth was first noticed at the age of 2 years. A trial administration of 3 grains (0.2 gm) of thyroid given at twelve hour intervals sent the pulse rate up to 92. Can I expect improvement in ossification and increase in height by thyroid medication alone? Would anterior pituitary medication (growth hormone) be indicated? A flat plate of the sella shows a normal outline. Any suggestions will be appreciated. Please omit name. MD Illinois

ANSWER—The clinical description suggests for a considerable part at least, a condition of hypothyroidism. The dosage of thyroid medication in these cases deserves the utmost consideration. Since the remedy is to be used for a long time, one should begin with small doses and determine the tolerance of the patient to the remedy. The basal metabolic rate is an excellent guide to dosage and should be repeated at intervals. In general, it is better to begin with 0.03 Gm of the thyroid preparation twice daily and increase the dose gradually until the optimal tolerance is ascertained. One cannot say beforehand what the dosage should be in an individual case but by beginning with the minimum dose and increasing cautiously, the best results will be obtained. There does not seem to be any indication for the use of pituitary medication.

GEOGRAPHIC TONGUE

To the Editor—A woman aged about 55 and apparently in good health has had an irritation and pain along the left border of her tongue for about a year. As her sister died recently from cancer of the tongue and mouth she is alarmed and worried. I find an oval area measuring three fourths by one half inch looking like a common ring worm with a normal appearance in the center. I have never seen or heard of a case of trichophytosis of the mucous membrane and I get no help from my books. I cannot demonstrate the organism but this is my diagnosis. How can the condition be treated? Solutions are washed away too soon to do any good. Please omit name. MD Iowa

ANSWER—Benign migratory plaque geographic tongue resembles a patch of ringworm at first glance but is not caused by a fungus. Its etiology is unknown. It comes and goes without apparent cause, the lesions form enlarge, pass along the tongue and disappear, and then a new one appears and goes through the same cycle. The border is sharply defined, gray to yellow. The center is normal in color and appearance. Normally there is no sensory disturbance connected with it. Worry about cancer, however often causes pain and these cases are very hard to cure. The best procedure would be to have a specialist see the tongue and make a diagnosis and then try to treat the worry.

LOW BACK PAIN AND SCIATIC NEURALGIA

To the Editor—A patient of mine a woman aged 56 has had sciatica for the past four months which apparently was due to a pelvic tumor. A laparotomy was performed about two weeks ago and a partly calcified intraligamentous ovarian cyst the size of a grapefruit was removed. Her condition improved after the operation and the constant pain subsided when she is at rest in bed. However when she sits up on a bed pan the pain reappears in the same buttock. The other day I had her sit up in bed but the pain was so bad that she had to lie down. I would like to know the prognosis in sciatic neuralgia due to a pelvic tumor. Should the pain disappear as soon as the tumor is removed? What may be the pathologic basis of the sciatic disturbance in this case? Should I wait until the pain disappears completely or should I give the patient an injection in the epidural space? Please omit name. MD New York

ANSWER—The pain should disappear shortly after the removal of the tumor. The pathologic change in the sciatic nerve is one of pressure neuritis. The pain in the buttock may be due to superior gluteal neuritis. The patient should have a neurologic followed by an orthopedic examination. A caudal epidural injection may relieve the patient of pain, but it is not differentially diagnostic of the etiology.

The term sciatica is one of the most loosely applied in medicine. Solis-Cohen of Philadelphia asks his class the question 'When is sciatica not sciatica?' The answer is nine times out of ten. The physician should consider postural defects, bone or muscle insufficiency, ligamentous stress and strain disease

of bone and spinal cord tumor. Roentgenograms of the lumbosacroiliac region might offer some interesting data.

If every gynecologist would make simple neurologic and orthopedic examinations before the operation that is held out as a promise of relief from low backache and the sciatic syndrome, there would be fewer persistent symptoms which may be embarrassing after the operation. Every gynecologist should be qualified to make these examinations. If he needs further help, the neurologist and the orthopedist can be called on.

DRY STERILIZATION OF OPHTHALMIC INSTRUMENTS

To the Editor—Can you give me any methods for the efficient sterilization of the more delicate instruments used in ophthalmologic surgery which will not produce erosion of the metal? Distilled water has been used but oxidation processes have occurred on the surface of these instruments. Would ordinary autoclaving be efficient? I would appreciate references to reports on this subject.

HAROLD FELDMAN, M.D., Quincy, Ill.

ANSWER—Dry sterilization of instruments for ophthalmic use is in great favor among certain operators, especially those of the French school. Morax (Precis d'ophtalmologie, ed 5 1931) advocates dry sterilization at a temperature of from 160 to 170 (probably centigrade) for twenty minutes and states that there is no injury to the points or cutting edges below a temperature of 180. For the killing of organisms he considers 150 degrees the lower limit. Ordinary autoclaving is sufficient for sterilization, but the procedure has a bad effect on the fine cutting edges so necessary in ophthalmic instruments. Many of the operators in this country run the noncutting instruments through the ordinary hospital autoclave and sterilize the cutting instruments by immersion for twenty minutes in compound solution of cresol. This is followed by an alcohol and sterile water bath. The rusting mentioned results from failure to dry the instruments properly after use. It will be found that if the cutting instruments are dried and then dipped into petrolatum the thin film that adheres will be sufficient to prevent any rusting.

IODIDE METHOD OF STARR FOR CARDIAC FUNCTION

To the Editor—Will you be kind enough to publish in Queries and Minor Notes the iodide method of Starr to determine cardiac function? Please omit name.

MD Punene Maui T H

ANSWER—It will be necessary for the correspondent to consult the original article in regard to this method. The reference is as follows:

Starr Isaac Jr and Gamble G J Improved Method for Determining the Cardiac Output in Man by Means of Ethyl Iodide *Am J Physiol* 87 450 (Dec) 1928

USES OF SODIUM THIOSULPHATE—BITTERS

To the Editor—Is sodium thiosulphate (hyposulphite) given internally for any other purpose than as an antidote for certain poisons? I would like other indications named if any are known. I would also appreciate information as to whether the use of bitter orange peel, serpentaria, stillingia, quassia and gentian is justified for any other purpose than as bitters. Please omit name.

MD Michigan

ANSWER—Sodium thiosulphate is employed in parasitic skin diseases as in the prevention and treatment of ringworm of the feet (15 per cent foot bath, 20 per cent in boric acid as dusting powder). It has also been used as a cathartic (1 Gm in water every two hours).

Bitter orange peel is a pleasant flavor. Serpentaria has the reputation of being a "stimulant" expectorant, an emmenagogue, and useful as a gargle in angina. Stillingia is a laxative and a diuretic, as well as an 'alterative' of possible use as an adjunct to the specific treatment of syphilis or of malaria. Quassia is a parasiticide of use against head lice and an anthelmintic against threadworms. In large doses it acts as a cathartic. Gentian combined with alkali is recommended in gastric and intestinal catarrhal conditions.

INTRACAPSULAR FRACTURE OF FEMUR

To the Editor—Please advise me whether it would be possible for a capillary fracture of the femur to heal so that no signs would show in a roentgenogram that was taken of the leg five weeks after the fracture.

C O CASEY, M.D., Decatur, Ill.

ANSWER—Thorough inquiry has failed to reveal such a thing as capillary fracture. Possibly intracapsular fracture is meant. It is possible that a fracture can unite so well after five weeks that a thorough roentgen examination will not show it.

New York June Examination

Mr Herbert J Hamilton, chief Professional Examinations Bureau, reports the written examination held by the New York State Board of Medical Examiners in Albany Buffalo, New York and Syracuse June 26 29 1933. The examination covered 19 subjects. An average of 75 per cent was required to pass. Five hundred and forty-two candidates were examined 452 of whom passed and 90 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed

* Verification of graduation in process

with him by the taxpayer. This application must contain a full recital of the causes for the delay. Failure to make a return may subject the taxpayer to a penalty of 25 per cent of the amount of the tax due.

The normal rate of tax on individual citizens or residents of the United States, under the Revenue Act of 1932, is 4 per cent on the first \$4,000 of net income in excess of the exemptions and credits, and 8 per cent on the remainder.

WHO MUST FILE RETURNS

1 Returns must be filed by every person having a gross income of \$5,000 or more, regardless of the amount of his net income or his marital status. If the aggregate gross income of husband and wife, living together, was \$5,000 or more, they must file a joint return or separate returns, regardless of the amounts of their joint or individual net incomes.

2 If gross income was less than \$5,000, returns must be filed (a) by every unmarried person, and by every person married but not living with husband or wife, whose net income was \$1,000 or more, and (b) by every married person, living with husband or wife, whose net income was \$2,500 or more. If the aggregate net income of husband and wife, living together, was \$2,500 or more each may make a return or the two may unite in a joint return.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changes during the year, the personal exemption and credit must be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless it amounts to more than half a month, in which case it is considered as a month.

As a matter of courtesy only, blanks for return are sent to taxpayers by the collectors of internal revenue, without request. Failure to receive a blank does not excuse any one from making a return. The taxpayer should obtain one from the local collector of internal revenue.

The following discussion covers matters relating specifically to the physician. Full information concerning questions of general interest may be obtained from the official return blank or from the collectors of internal revenue.

GROSS AND NET INCOMES WHAT THEY ARE

Gross Income—A physician's gross income is the total amount of money received by him during the year from professional work regardless of the time when the services were rendered for which the money was paid, plus such money as he has received as profits from investments and speculation, and as compensation and profits from other sources.

Net Income—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year, as stated before. These matters are fully covered in the instructions on the tax return blanks.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The following statement shows what such deductible expenses are and how they are to be computed.

Office Rent—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as

Medical Economics

THE PHYSICIAN'S INCOME TAX—1934

The following instructions are based on the Revenue Act of 1932. That act, unless the congress now in session modifies it, will govern the collection of federal income taxes for the tax year 1933. It is believed likely, however, that Congress will modify the present law. What those modifications will be if there are any, and to what extent they will call for a procedure materially different from that required by the Revenue Act of 1932, no one can foretell. Two courses are open to the physician. He may file his income tax return at once for 1933, on the basis of the Revenue Act of 1932, and then, later, if new legislation so requires, he may make a supplementary return. If he prefers, however, he can wait until toward the close of the period allowed for filing returns, which is March 15, and then file his return in accordance with the legislation then in force. The choice between these two plans had best be determined by each physician to suit his own convenience.

The taxpayer who is required to make a return must do so on or before March 15, unless an extension of time for filing the return has been granted. For cause shown the collector of internal revenue for the district in which the taxpayer files his return may grant such an extension on application filed

a residence as well as for office purposes he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in his dwelling house or apartment he may not, however, deduct any part of the rent of such house or apartment as professional expense, to entitle him to such a deduction he must have an office there with regular office hours. If a physician owns the building in which his office is located he cannot charge himself with rent and deduct the amount so charged.

Office Maintenance—Expenditures for office maintenance as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using for instance dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies, and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment the useful life of which is short, may be deducted, but if such articles have a more or less permanent value their purchase price is a capital expenditure and is not deductible.

Equipment—Equipment comprises property of more or less permanent value. It may ultimately be used up, deteriorate or become obsolete, but it is not in the ordinary sense of the word consumed in the using; rather, it wears out.

Payments for equipment or nonexpendable property for professional use cannot be deducted. As property of this class may be named automobiles, office furniture, medical, surgical and laboratory equipment of permanent value and instruments and appliances constituting a part of the physician's professional outfit and to be used over a considerable period of time. Books of more or less permanent value are regarded as equipment, and the purchase price is therefore not deductible.

Although payments for equipment or nonexpendable articles cannot be deducted, yet from year to year there may be charged off against them reasonable amounts as depreciation. The amounts so charged off should be sufficient only to cover the lessened value of such property through obsolescence, ordinary wear and tear, or accidental injury. If improvement to offset obsolescence and wear and tear or injury has been made and deduction for the cost claimed elsewhere in the return claim should not be made for depreciation.

A hard and fast rule cannot be laid down as to the amount deductible each year as depreciation. Everything depends on the nature and extent of the property and of the use to which it is put. Five per cent a year has been suggested as a fair amount for depreciation on an ordinary medical library. Depreciation on an automobile would obviously be much greater. The proper allowance for depreciation of any property is that amount which should be set aside for the tax year in accordance with a reasonably consistent plan not necessarily at a uniform rate, whereby the aggregate of the amounts so set aside, plus the salvage value, will at the end of the useful life of the property in the business equal the purchase price of the property or if purchased before March, 1913, its estimated value as of that date or its original cost, whichever may be the greater. The physician must in good faith use his best judgment and make such allowance for depreciation as the facts justify. Physicians who, from year to year claim deductions for depreciation on nonexpendable property will do well to make annual inventories as of January 1 each year.

Medical Dues—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

AUTOMOBILE

Payment for an automobile is a payment for permanent equipment, and is not deductible. The cost of operation and repair and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tire, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeurs' wages, etc.

Deductible loss through depreciation is the actual diminution in value resulting from obsolescence and use, and from accidental injury against which the physician is not insured. Its depreciation is computed on the basis of the average loss during a series of years; the series must extend over the entire estimated life of the car, not merely over the period in which the car is in the possession of the present taxpayer.

If the automobile is used for professional and also for personal purposes—as when used by the physician for recreation, or used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses. He is regarded as using his car for his personal convenience and not as a means of gaining a livelihood.

What has been said with respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Laboratory Expenses—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of other corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire, etc.—Loss of and damage to a physician's equipment by fire, theft or other cause not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits—Expenses incurred in the defense of a suit for malpractice are deductible as business expense.

Sale of Spectacles—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

Book Notices

The Diseases of Infants and Children By J. I. Crozer-Griffith M.D., Ph.D. Consulting Physician to the Children's Hospital Philadelphia and A. C. Mitchell M.D. B. K. Bachford Professor of Pediatrics College of Medicine University of Cincinnati Third edition Cloth Price \$10.15 with 281 illustrations Philadelphia & London W. B. Saunders Company 1933

This edition is in one volume but is more than a mere condensation of material. Almost every recent advance in pediatrics since the last edition has been included. One of the features of the former edition was the well selected bibliography offered after the discussion of each subject. This has been revised to include only those historical references which are pertinent to the discussion and a large amount of new pediatric literature. The previous editions enjoyed a well deserved popularity among practitioners of medicine, but because they appeared in two volumes the use of the work for undergraduates was limited. The present edition should serve the practitioner and the student equally well. The work is one of the most comprehensive treatises on diseases of infants and children available in one volume. The material is clearly presented and the discussions are to the point. Therapeutic measures receive adequate consideration and are presented in a rational and practical manner. The book is highly recommended as a reliable source of information and as a well organized and systematic discussion of pediatric subjects adapted to the needs of the student.

Lehrbuch der Gynäkologie Von Prof. Dr. W. Stoeckel Geh. Med. Rat Direktor der Universitäts-Frauenklinik zu Berlin Fourth edition Paper Price 33 marks Pp. 748 with 527 illustrations Leipzig S. Hirzel 1933

In spite of the fact that the third edition appeared only two years ago, the present book is called the fourth edition and advertised as having been newly revised. However, the reviewer, after a fairly careful search, was able to find only a few new illustrations among the 462 illustrations in the text and the 65 colored plates. Furthermore, the wording in the text compared at random in more than fifty different parts of the book was exactly identical except in few instances. In other words, the present edition is almost an exact reprint of the previous edition except for the slight shifting in the numbering of the illustrations and for additional information in the section on carcinoma of the uterus. However, what was said in the review of the third edition (*THE JOURNAL*, Sept. 5, 1931, p. 730) holds true today. Stoeckel's book is still the best single volume in gynecology published in the German language.

The Eugenic Predicament By S. J. Holmes Professor of Zoology University of California Cloth Price \$2 Pp. 232 with 4 illustrations New York Harcourt Brace & Company 1933

The title expresses the author's conviction that the present dysgenic differential birth rate, through which those elements of the population whose perpetuation is least to be desired have the most children, is indeed a predicament. "We are forced to conclude that the more intelligent are being outbred by those on a lower mental level." A number of writers have exercised their ingenuity to discover reasons for not accepting this unpleasant conclusion. Others who admit that the present differential birth rate is dysgenic contend that it is nothing to be disturbed about. With the latter the author takes issue in a vigorous and yet temperate manner. He believes that heredity is a far more potent influence than environment in the ultimate development of individual capacity at least in limiting the progress which a given individual can make. He strengthens his position by freely admitting that nurture is important though less so than nature. He acknowledges that genius may be smothered by lack of opportunity, but he has no patience with those who hold that genius may spring full blown from a morose heredity. He sees the tendency of our racial development growing increasingly dysgenic. He disclaims for sensible eugenicists, any desire to see human marriages regulated "by a board" in the sole interest of eugenics but he does make a plea for a sensible recognition of the sufficiently obvious fact that certain types of individuals ought not to be permitted to reproduce their kind. This negative approach,

he holds, should be supplemented by a positive one, in the form of an effort, admittedly difficult and complicated, to induce persons with superior hereditary endowments to have more children. He discusses the plan of family allowances, based partly on earnings of the parents, as a means of encouraging greater fertility. By eliminating the very rich, to whom inducements of a financial nature presumably would not be significant, and the very poor, on the theory which he holds that habitual poverty is more or less *prima facie* evidence of inefficiency, and by laying the burden on industry through cooperative pooling plans in which the proposed beneficiaries will participate, he believes that a system can be worked out. Whether or not one shares the author's optimism concerning the chances for success of unselfish cooperative efforts which cost somebody money with no immediate return in sight, no sensible person can disagree with his main premise, that the birth rate is racially destructive and that something ought to be done about it. The book is well written, well documented, well printed. Intelligent lay persons will find it instructive and valuable. It should be read especially by those who are interested in social welfare movements.

Measles Report of the Medical Officer of Health and School Medical Officer on the Measles Epidemic 1931-32 London County Council Publication No. 2996 Paper Price 2s. 6d. Pp. 112 with one illustration London London County Council P. S. King & Sons Ltd 1933

This report deals with an epidemic of measles occurring from November 1931 to August 1932. It discusses the incidence of the epidemic, its mortality and hospital treatment. The conclusion is reached from the experience in the epidemic that when children can be suitably housed at home and can be provided with proper nursing care they have better chances of making a complete and rapid recovery without the development of complications than in a hospital. However, when such conditions cannot be met, early removal to a suitable hospital is urged. It is stated that many years' experience has definitely proved that the older methods of control by complete school closure or partial exclusion of susceptibles can show nothing in their favor and must be abandoned in favor of the modern and more scientific method of close daily surveillance of the school by the school nurse and of the home by the health visitor. Serum treatment was applied on an extensive scale. The conclusion was reached that serum has no effect in diminishing the severity of the attack or in preventing the development of complications after the disease has been established. However, if given in sufficient quantity within four days from exposure it will entirely prevent the disease, and if given from the fourth to the seventh day after exposure, or earlier in insufficient doses, it will render the disease extraordinarily mild. It was found that adult serum is only slightly inferior to convalescent serum in its protective and attenuating action. The method of collecting and storing and administering serum is discussed in detail. To those having to do with epidemics of measles, this report will be very helpful. It shows what can be accomplished in a practical way by intelligent application of scientific methods.

Histology By S. Ramón Cajal M.D. F.R.S. LL.D. Director Royal Cajal Institute for Medical Research Revised by J. F. Tello Muñoz M.D. Professor of Pathology University of Madrid Authorized translation from the tenth Spanish edition by M. Fernán Núñez M.D. Professor of Pathology Marquette University Medical School Cloth Price \$8 Pp. 738 with 535 illustrations Baltimore William Wood & Company 1933

Professor Ramón y Cajal has contributed more to the understanding of the structure of the nervous system than any other scientist ancient or modern, and no one has extended his inquiries over a wider field in general histology. All teachers of the subject will be interested to know his method of presenting the material to elementary students. He regards the course as a fundamental biologic discipline, not as a preparatory course for pathology. The cell is therefore thoroughly discussed from a dynamic point of view. Half of the book is devoted to a consideration of elementary tissues. The whole field of microscopic anatomy is covered but the descriptions of most organs are greatly condensed. The nervous system, however, is described in detail, nervous tissues and neurohistology comprising about a third of the total. As is to be expected in a work often revised, there are some discrepancies between figures

and text and similar inconsistencies. Naturally the results of the metallic impregnation methods are stressed for they have reached their highest development in his hands and those of his students. It is worth calling attention to the fact that few outside his school have realized the value of the Golgi apparatus in differentiating cell types. Cajal's period of active investigation is almost coextensive with that of modern histology, and his allocations of credit for fundamental discoveries are authoritative, sometimes they differ from those usually made. The translation is such that it is not likely to be recommended to beginners in this country. Many important recent advances in histology are not touched on. In all too many instances the translation completely obscures the original meaning. Thus, on page 208 one reads that 'chondrin is a mixture of chondrotic acid, albumin, cholin (glue)', on page 320, the nerve terminations are 'except of myelin and composed of glandular cells' with regard to the glia of the vertebrate optic nerve (p. 373) 'these cells in the spider possess' and on page 480 'the grafts should be of the very small ganglia of the tail of a horse (new born dog cat or rabbit)'. The literal translations perhaps add a certain picturesqueness, with which, however, all investigators are familiar and which are apt to confuse the beginner e. g. 'intestinal dermis,' 'evolution' for development 'preexistence' for preformation (which, by the way, Cajal emphatically denies) 'the callous body,' 'visceral and parietal leaves'. Lenhossék and Henneberg emitted the hypothesis, 'bundles of nerve fibers march between preages of cells,' 'the other centrosome emits a long filament which emerges from the spermatid and represent the sketch of the zoospermatid tail'. It is difficult to see any reason for coming English words from the verb 'ausstrahlen' or for persistently misspelling the names of certain authors. Typographic errors are not common. The illustrations are mostly originals, drawn in the clear crisp manner of Cajal occasionally with labeled structures unexplained in the legend. Credit is not always given for borrowed illustrations.

Experimentelle Studien over den overførbare hønseløkose (mit deutscher Zusammenfassung) [Experimental Studies on Transmissible Leukosis in Chickens] Af J. Engelbreth Holm. Paper. Pp. 161 with 40 illustrations. Copenhagen. Levin & Munksgaard 1933.

This is a dissertation by a candidate for the degree of doctor of medicine in the University of Copenhagen. It deals with transmissible leukosis in chickens, a disease or group of diseases of wide spontaneous occurrence the cause and spread of which is not understood. There are two main forms, the myeloid or myelosis, which resembles human myeloid leukemia, and the erythroblastic or erythroblastosis, in which develop large numbers of immature erythroblasts. Both forms resemble neoplasms much more than inflammatory or infectious processes. Both are transmissible by means of affected cells and also cell-free plasma from diseased chickens. The dissertation will be of interest to all who are concerned in any way with the study of leukosis and allied diseases.

What We Are and Why. A Study with Illustrations of the Relation of the Endocrine Glands to Human Conduct and Dispositional Traits with Special Reference to the Influence of Gland Derangements on Behavior By Laurence H. Mayers, M.D. and Arthur D. Welton. Cloth. Price \$3.15. Pp. 340 with illustrations. New York. Sears Publishing Company, Inc. 1933.

Here is a romance on endocrinology which has a unique purpose. It not only presumes to inform the reader on the physiologic implications of the endocrine secretions but it attempts to show the relation of the endocrine glands to human conduct. Illustrated serial case reports accompany the text. The author appreciates that the entrance in the field of endocrine psychology is venturesome but he apparently has decided that such an attempt should be made. There is reason to believe, however, that his purpose will not receive justification in this book. To the average lay reader, mumps will be dredged as a disease that made a dancing boy of Donald and relegated Clara to a drab existence. While this may be one method of calling the attention of the public to the fact that mumps is not always an insignificant infection, it is not the most desirable. It can do nothing more than instill an anxiety about the endocrine system that scientific medicine cannot pacify. The layman's enthusiasm for endocrinology is already far in advance of scientific knowledge.

Orthopädische Gymnastik Von Prof. Dr. med. Georg Hohmann, Direktor der Orthopädischen Universitätsklinik, Frankfurt a. M. und Lea Stumpf, Lehrerin für Heilgymnastik und Massage an der Universitätsklinik Frankfurt a. M. Boards. Price 7 marks. Pp. 156 with 241 illustrations. Leipzig, Georg Thieme 1933.

Prof. Georg Hohmann, director of the orthopedic clinic of Frankfurt University, collaborated with Lea Stumpf, instructor of gymnastics at the same clinic, in the preparation of this excellent book. The authors have clearly presented their views of the problems concerned in the treatment of the various postural variations and deformities of the back and extremities. The most important chapters are on the round back, sway back and scoliosis. There is a chapter on the paralytic, contractures of the limbs and war injuries and other disabilities. By means of line drawings and photographs they have depicted various exercises and mechanical devices that assist the patient in performing the corrective exercises. The instructive illustrations reveal at a glance the nature and method of the corrective exercise.

The Human Problems of an Industrial Civilization By Elton Mayo. Professor of Industrial Research, Graduate School of Business Administration, Harvard University. Cloth. Price \$2. Pp. 191. New York. Macmillan Company 1933.

The first efforts to treat human problems were by applying broad generalizations to specific situations. Fatigue was traced to the increase of toxins in the blood and was measured by declining output. Wide individual variations threw doubt on the generalizations and led to the conclusion that fatigue and monotony were not definite entities but were more like relations arising from the attitude of individuals to all their environment and hence could be treated only after individual and social diagnoses. An elaborate five year experiment in the Hawthorne General Electric Works finally involved psychiatry, anthropology, economics and the related sciences in the effort to diagnose and treat the problems of five individuals. The author follows the problems that arose in this study out into society, calling to his aid the allied sciences as they are being coordinated in the recently established Harvard Graduate School, and concludes that the conflicts discovered at Hawthorne are characteristic of the entire social structure, and that the elite of the several civilized powers is at present insufficiently posted in the biological and social facts involved in social organization and control. So we are compelled to wait for the social organism to recover or perish without adequate medical aid. This is one of the most fundamental action as well as thought provoking analyses of present difficulties that the present situation has produced.

Handbook of Chemotherapy By Dr. Viktor Fischl, Department Director of the Schering-Kahlbaum A. G. Berlin and Prof. Dr. Hans Schlossberger, Member of the Reich Board of Health, Berlin. Dahlem. Part I. Metal Free Organic Compounds. English translation from the German by A. S. Schwartzman. A. B. M. D. Cloth. Price \$8.50 per set of 3 volumes. Pp. 410. Baltimore. H. G. Roebuck & Son 1933.

The English translation of the German edition will be welcomed by others as well as by the investigator in chemotherapy, particularly as a source of information. The volume is everything claimed for it in a review of the original German which appeared in these columns Oct. 29, 1932. This volume constitutes the first of three books comprising a complete set. The publishers have advised that volumes 2 and 3 will follow as soon as receipt of the German manuscript and translation will permit.

The Science of Radiology By various contributors. Edited by Otto Glasser, Cleveland Clinic Foundation. [Authorized by the American Congress of Radiology.] Cloth. Price \$1.50. Pp. 450 with 108 illustrations. Springfield, Ill. & Baltimore. Charles C. Thomas 1933.

Dr. Otto Glasser and his collaborators, of whom there were twenty-five, limited themselves essentially to contributions of American co-workers, preserving the individuality of the contributions and making alterations only to maintain uniformity in the text. This work was ably done and, considering the size of the book, many notable achievements and valuable data have been crowded into its pages. The contributing editors were carefully selected, their names being sufficient warranty to assure quality consistent with conciseness. The chapters deal with historical sketches of Wilhelm Conrad Roentgen, the Curies, American pioneers, radiologic societies, physics of

radium and roentgen rays, apparatus dosimetry, radiologic diagnosis, military roentgenology, radium and roentgen therapy, biologic effects, protection, teaching of radiology, cosmic rays and the Gurnitsch rays. All the chapters are written in such a way as not to become tedious. Every radiologist or allied worker should possess a copy, especially for its historical value.

Röntgendiagnostik der Knochen und Gelenkkrankheiten. Von Professor Dr. Robert Kleinbock. Heft 1. Differentialdiagnose der geschwulstigen Knochenkrankheiten. (Abteilung Knochenkrankheiten.) Paper. 160 pages. 5.00 marks. 1 p. 103 with 26 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1937.

The subjects considered are multiple osteoma, multiple chondroma, multiple osteochondroma, osteogenic sarcoma, cystic fibroma, osteitis fibrosa cystica, von Recklinghausen's disease, multiple scleromatous, multiple myeloma, Ewing's sarcoma, multiple xanthoma, and metastatic carcinoma. All these subjects are discussed clearly and succinctly and are illustrated by excellent roentgenograms.

Medicolegal

Malpractice Failure to Make Preoperative Examination, Delegation of Professional Duty—The defendant-physician removed the tonsils of the plaintiff's husband, under general anesthesia. The husband died four or five days thereafter, the death certificate stating the cause of death to be "Acute dilatation of heart following anesthetic for tonsil operation." In this suit, the plaintiff alleged that the defendant so negligently performed the operation and so negligently failed to treat and care for the patient after the operation that death ensued as a proximate result. The trial court gave judgment for the plaintiff and the defendant appealed to the Supreme Court of Alabama.

The plaintiff testified that no preoperative examination was made of her husband by any one despite the fact that she told the defendant that her husband had recently had influenza and suggested that his heart had better be examined. Whether any preoperative examination was made and whether such examination would have disclosed the patient not in condition for an operation under general anesthesia, at least without the preparatory treatment indicated by the medical witnesses, were questions for the jury. The defendant argued however, that the complaint did not charge negligence in the matter of a preoperative examination, that the negligence charged was limited to the actual operation on the operating table and to the after-treatment. But said the Supreme Court, a preoperative examination is incident to an operation and reasonably necessary, in the nature of a diagnosis, determinative of the propriety of the surgical treatment employed. The undertaking to remove the tonsils by an operation includes such preoperative examination, just as an allegation of negligence in "treatment" of disease includes negligence in examination and diagnosis as well as application of remedies. The defendant seemed to rely on evidence tending to show that preoperative examination in cases of removal of tonsils is a part of the regular routine in hospitals, such examinations being made as a routine by the house physician or intern and that an intern informed him, prior to the operation that an examination of the patient had been made, showing the patient in proper condition for the operation. The defendant was not authorized said the Supreme Court, to assume that a proper examination had been made and that the patient had been found in proper condition before being brought to the operating room. The evidence of the plaintiff, if believed tended to show such notice to the defendant calling for inquiry on his part as to present a jury question of want of due care in assuming a proper examination had been made if he did so assume. If an intern did report to the defendant that the patient was in good condition for the operation the question arises said the court concerning the liability of surgeons for negligence of others holding licenses to practice their respective professions or specialties. Broadly speaking, the inquiry in each case involves the scope of the undertaking of a physician and surgeon when

a patient comes to him to treat his ailment, having contractual relations with no one else. Just rules for the protection alike of the profession and of the public, in line with general principles of law, should be the end sought in all cases. Whether another member of the profession is to be treated as the agent of the employed physician, under the doctrine of respondeat superior, or whether the physician should be held to reasonable care only in the selection of competent persons, to whom he may commit important portions of the work he has undertaken, must turn much on the particular case, and maybe on the course of practice among responsible physicians in the general neighborhood. It cannot be said as a matter of law that the defendant exercised reasonable care in acting, if he did, on a wholly fabricated report.

We see no reason to hold, continued the court, that after-treatment immediately following the operation, while the patient's reaction to the operation is still in doubt, is not within the original undertaking of the physician and surgeon. The evidence tends to show that the defendant did recognize such obligation and undertook such treatment. The evidence here again presented a jury question touching negligence in this regard. In Alabama, the doctrine of *res ipsa loquitur* does not apply in malpractice cases. Unfavorable results, standing alone, unless in cases of palpable misconduct within common knowledge, are not evidence of negligence which will shift the burden of proof to the defendant. The Supreme Court, after considering all the assignments of error, could find no error and the judgment of the trial court against the physician was affirmed—*Stephens v Williams (Ala)*, 147 So 608.

Administration of Anesthetic as Medical or Surgical Treatment—The Order of United Commercial Travelers agreed to pay the appellee a certain sum if her son, a member of the order, died from bodily injuries effected through external violent and accidental means. The order was not to be liable for any death resulting from medical, mechanical or surgical treatment except where the surgical treatment was made necessary by an accident. The son consulted physicians for the purpose of having his posterior urethra examined. Butyn was administered. Immediately the son had convulsions and died within a few minutes. In this suit against the order, the district court gave judgment for the mother, and the order appealed to the United States circuit court of appeals, eighth circuit. In giving judgment against the order, said the circuit court of appeals, the district court overlooked the distinction between an accidental result and the result of an accidental cause or means. The means employed in the case under consideration was the administration of the drug butyn. There was nothing in the act of administering the drug that was unintended or unexpected. There was no showing that the drug did not produce the intended result. But another result was produced, owing to the idiosyncrasy of the patient. The administering of the butyn was the means, the causative agency, employed by the physician, the idiosyncrasy was but the condition that existed and was inherent in the patient. There was no accidental means but simply an unexpected or accidental result. The administration of the butyn did not cause the idiosyncrasy and if the bodily injury that resulted in death was produced by the idiosyncrasy as a cause or means, then the administration of the drug was not the sole cause. Furthermore said the court, the idiosyncrasy would be neither a violent nor an external means.

The drug butyn was concededly administered to the son by a physician of good standing. It was administered for the lessening of pain to the patient during a preliminary examination of the posterior urethra. It was a drug commonly used by physicians for such a purpose. The usual and proper amount of the drug was used, and it was properly administered. We think, said the court of appeals the administering of the drug must be placed in the category of medical or surgical treatment. The meaning of the word "treatment" as used in the policy must be given a reasonable scope. It includes not merely the actual operation in a surgical case or the giving of a prescription in a nonsurgical case but also the preliminary examination including sometimes an exploratory operation or exploratory examination. Whatever is usually done to the

patient or administered to him by a skilled physician or surgeon is properly included under the term 'treatment,' even though it may not be an indispensable prerequisite. If the administering of the butyn in the present case did not constitute medical or surgical treatment, said the court, we should be at a loss how to classify such act. The judgment of the district court against the order was reversed.—*Order of United Commercial Travelers of America v. Shann*, 61 Fed. (2d) 55.

Insurance "Poisoning or Bacterial Infections" Construed—The defendant insurance company insured the life of the appellee's husband. It promised to pay double indemnity if death resulted from a bodily injury effected solely through external, violent and accidental means but only the face of the policy if death resulted from poisoning or bacterial infections. It was agreed that the insured met his death by insecticide poisoning which contained forty per cent nicotine sulphate and that his death was accidental. The insurance company admitted liability for the face amount of the policy but refused to pay double indemnity. In the U. S. district court district of Nebraska the wife obtained judgment for double the face amount of the policy and the company appealed to the U. S. circuit court of appeals eighth circuit. The crucial question said the appellate court is whether the word 'poisoning' in the phrase italicized creates an independent exception to liability or merely qualifies the word 'infections' as does the word 'bacterial'. The insurance company contended that the word 'poisoning' is either a noun or a participle. A court may take judicial notice of the meaning of words given in standard works such as dictionaries. In *A New English Dictionary* by James Murray (Oxford) vol. 7 p. 1058 and in *Wright's English Dialect Dictionary* vol. 4 p. 569 is found authority for the use of the word poisoning as a participial adjective. In both dictionaries, one of the definitions of 'poisoning' is given as 'poisonous'. In the realm of medicine, there are poisoning infections which are not bacterial. Sporotrichosis and actinomycosis are infections by fungi so recognized and described in *Dorland's American Illustrated Medical Dictionary* (ed. 14), 1927. Further, if poisoning were used as a noun, it is reasonable to assume that the word 'from' would have been repeated before the word 'bacterial'. The court concluded that the word 'poisoning' qualified the word 'infections' in the clause in controversy and that the cause of death of the insured was not excepted from the double indemnity provisions of the policy. The judgment of the district court in favor of the wife was affirmed.—*Northwestern Nat. Life Ins. Co. v. Banning*, 63 Fed. (2d) 736.

Workmen's Compensation Acts Compensability of Pneumonia—The employee, in the course of his employment with the plaintiff company, was subjected to sudden changes in temperatures. He contracted lobar pneumonia from which he died. A proceeding was instituted by his widow for compensation under the workmen's compensation act. From an award of compensation, the plaintiff company appealed to the Supreme Court of Illinois. The evidence in this case, said the Supreme Court, is undisputed that the cause of death was lobar pneumonia. To justify an award under the workmen's compensation act for the death of an employee it must be proved by evidence from which at least the inference can be fairly and reasonably drawn that the deceased received an accidental injury which arose out of and in the course of his employment, which caused his death. It was argued that the great difference in temperature caused a thermal injury to the employee's lungs, which was the cause of lobar pneumonia and that his death was directly caused by that injury. Liability under the compensation act, said the court, cannot rest on speculation and conjecture but must be based on facts established by a preponderance of the evidence. There was no evidence that an injury was sustained by the employee or that the conditions under which he worked gave rise to the presence of pneumococcus germs, or when, during such employment, a so-called thermal injury took place. The record was barren of proof that the employee received any injury prior to the time when he was seized by lobar pneumonia. While the medical witnesses testified that in their opinion there was a causal relation between the employee's death and the conditions under which

he worked none testified as to what that causal relation was when it was manifested, or when the employee became infected with the lobar pneumonia. On the other hand, they stated that they could not fix the time when he became so infected or injured. It is a matter of common knowledge that many people go from a hot room into a cold temperature outside, contracted the court without contracting lobar pneumonia, and that on the other hand many are afflicted with lobar pneumonia who do not experience such a change in temperature. The employee might have acquired pneumonia from one of numerous causes and under numerous conditions or circumstances. The inference on which an award may be based must be a reasonable one based on facts established by evidence fairly tending to prove them. There was no proof that the pneumococcus germs were present at the place and under the conditions of the employee's employment or that the conditions of his employment were conducive to the presence of such germs. The proof does not show that the deceased received an injury which arose out of and in the course of his employment which caused pneumonia resulting in his death. Therefore concluded the court, the trial court erred. The judgment of the trial court was reversed and the award set aside.—*Ill. Prouty Co. v. Industrial Commission (Ill.)*, 185 N. E. 267.

Malpractice Failure to Remove Surgical Needle After Appendectomy—The defendant physician operated on the plaintiff for appendicitis, Aug. 8, 1928. For many months thereafter the plaintiff was troubled with soreness and pain in his side. He consulted the defendant who gave him internal medicine and advised him to wear an abdominal belt and to have his tonsils removed. The condition of the plaintiff did not improve. Subsequently he consulted another physician, and a roentgenogram revealed the presence of a curved surgical needle imbedded in the region about the appendectomy scar. The needle was removed Sept. 4, 1929. In a suit for damages the trial court gave judgment for the plaintiff and the physician appealed to the Supreme Court of Michigan. He contended that the judgment of the trial court was based on conjectures and inferences that there was no evidence to show how the needle got into the plaintiff's body, that there was no evidence by physicians or surgeons that the defendant's acts were not in accordance with the recognized standards of practice by the profession and that in malpractice cases such evidence is necessary to establish negligence. In the majority of malpractice cases said the Supreme Court, the professional standard of practice is necessarily involved and requires testimony of competent experts. But in this case there was no question of skill or judgment, no question of practice beyond the knowledge of laymen. It was not necessary for the plaintiff to show that it was not good practice among surgeons in performing operations to sew up an incision without removing a needle. The finding of the trial court as to when and how the needle got into the plaintiff's body, continued the court, does not rest on conjecture. Counsel for the defendant made the following concession when the case was in the trial court: 'We can agree on the record that plaintiff's abdomen had not been operated on prior to the appendectomy by Dr. Asselin and it is not our claim that the needle entered plaintiff's body from any other source.' Apart from this concession said the court, the only possible inference from the proved facts is that the needle was left in the wound by the defendant. In the absence of some explanation by him sewing up the incision without removing the needle was negligence. The Supreme Court could find no error in the judgment of the trial court and that judgment was affirmed.—*Le Fave v. Asselin (Mich.)*, 247 N. W. 911.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Review of Sympathetic Ganglionectomies—Flothow and Swift state that sympathetic ganglionectomy is successful in properly selected cases of Raynaud's and Buerger's disease, scleroderma and other conditions in which vasospasm is present. In properly selected cases of chronic atrophic arthritis it affords considerable relief but has not proved to be the panacea that early reports might indicate. The lumbar operation is highly successful in Hirschsprung's disease and in chronic disabling constipation. There have been no failures in this type of case. In cases of spastic paraplegia of the lower extremities due to birth injury the operation is well worth while in carefully selected cases. In spasticity of the upper extremity it is of little or no value. Traumatic sympathalgia is offered as a name for those painful conditions caused by trauma and mediated by sympathetic nerves. The results in this type of case are excellent. Operations in cases of painful amputation stumps are rarely successful. In the majority of these cases there is a central type of pain. The suitable cases may be determined by diagnostic injection. Some cases of atypical facial pain may be relieved by sympathetic ganglionectomy. The authors report a group of miscellaneous conditions in most of which the results were not successful. Diagnostic injection is indicated to select cases suitable for operation. With the benefit of this procedure they feel that unsuccessful cases of sympathetic ganglionectomy should be rare in the future. The mortality of the extraperitoneal lumbar approach has been nil. Only one dorsal gan-

glionectomy has resulted fatally, in a severe case of angina pectoris.

Pyloric Obstruction—Feldman observed pyloric obstruction in slightly more than 0.01 per cent of all gastro intestinal roentgen examinations and in approximately 10 per cent of all organic lesions involving the pyloroduodenal outlet. Roentgenologically, it is not always possible to distinguish between ulcer and carcinoma in cases of pyloric obstruction. Gastric dilatation and the degree of gastric retention cannot be considered an aid in the differential diagnosis between ulcer and carcinoma. There is no roentgenologic basis for the assumption that a dilated stomach is more likely to be due to a benign obstructive lesion or that an obstructive normal sized stomach may be due to a malignant disease. The presence of a tumor mass is an important sign of a malignant condition, but this too is not always demonstrable. The roentgen examination, though extremely important in the diagnosis of this complication, must be considered together with other factors in order to establish the final diagnosis.

Sodium Morrhuate in Treatment of Varicose Veins—Cooper reports his results with sodium morrhuate in the treatment of varicose veins in more than 600 patients with about 4,000 injections. The only untoward reaction noted in his early use of 5 per cent sodium morrhuate was an occasional mild to moderate dermatitis with annoying pruritus. The patients presenting this complication had been treated with large quantities (10 cc) of the solution. Since limiting the quantity injected at one visit to 5 cc the author has rarely seen this complication occur. Occasionally, an injection of sodium morrhuate in 5 per cent strength is followed by a rather widespread reaction in and around the vein, characterized by infiltration, thickening, tenderness and reddish discoloration. This reaction may extend for a distance as great as 18 or 20 inches along the course of the vein, suggesting a rather widespread phlebitis and periphlebitis but the patient has no chills or febrile reaction and in a few days the swelling and tenderness begin to subside. In the author's opinion this reaction merely presages an excellent and thorough obliteration of the vein. Not one case of ulcer or sloughing due to the injection has occurred in his series of cases. A comparison of the results obtained with sodium salicylate, quinine hydrochloride and ethyl carbamate and with 5 per cent sodium morrhuate leads him to conclude that sodium morrhuate is more effective, safer and attended with fewer dangers and complications than the other agents.

Improved Gallbladder Technic—When cholecystectomy has been decided on, De Courcy usually elevates the gallbladder rest under the patient about 4 inches. The cystic duct is

grasped between two curved hemostats and is cut through. The stump is then tied with single number 2 chromic gut and is allowed to drop. All the adjacent tissues should be stripped away from the cystic duct before it is tied. With the duct stripped clean before ligation, drainage does not occur. The cystic artery is tied. A satisfactory ligation may be made by passing a suture on a curved needle through both layers of the peritoneum sufficiently deep to insure tying off of the artery. The suturing is then continued upward as the gallbladder is removed with sharp dissectors, starting from the duct end and working toward the blind end. When the gallbladder is stripped, a little peritoneum is left on each side to allow these edges to be sutured over the raw surfaces of the liver after the gallbladder is removed. The author is convinced that drainage tubes are a source of irritation and frequently incite drainage from a healthy wound. It has been his experience that seepage has not occurred when drainage tubes have been omitted. During the past three years he has omitted drainage tubes in a large proportion of cholecystectomies in which the common duct was not opened. He has used drainage only in cases in which it has not been possible to preserve a perfect operating technic. Drainage must be used when enough peritoneum cannot be preserved to cover the stump of the cystic duct and the raw bed of the liver from which the gallbladder has been enucleated and in cases in which it becomes necessary to drain the common bile duct. To discover whether or not there are any foci in the wound oozing bile or blood before the abdomen is closed, a gauze sponge is moistened with saline solution and poked lightly over every portion of the operating field so as to secure an impression on it of any oozing surfaces. If examination of the gauze shows blood or bile stains, the exact location of the oozing may be ascertained by the application of a fresh sponge. If the seepage cannot be repaired sufficiently, drainage should be used. The author concludes that cholecystectomy without drainage permits a shorter and more comfortable convalescence, insures maintenance of the biliary flow into the gastric tract during convalescence with fewer digestive symptoms and is unattended by many of the inconveniences that hinder recovery when drainage is utilized.

Leeches in Treatment of Phlebitis—Mahorner and Ochsner used leeches in the treatment of four cases of phlebitis. One was a case of thrombo-phlebitis obliterans in which there was a recent thrombosis of the popliteal vein. The number of leeches applied was inadequate and without benefit. In three cases of phlebitis occurring in men, the application of leeches resulted in rapid abatement of the symptoms and an early cure. The good effects of the leech treatment of phlebitis are: (1) rapid disappearance of pain, (2) disappearance of tenderness, (3) subsidence of edema, (4) softening of the clot and disappearance of objective evidence of its presence when the thrombosis is not too long standing, (5) subsidence of fever, (6) shortened duration of phlebitis and (7) marked decrease in the danger of pulmonary embolism. The authors recommend the leech treatment as the best available method of treating phlebitis and of diminishing the dangers of pulmonary embolism.

Arterial Embolectomy—Danzis states that, in embolus, early recognition and prompt surgical intervention give the best results. The operation should be done under regional or spinal anesthesia. Much better results are obtained in operations on the vessels of the upper extremity than on those of the lower. Collateral circulation plays an important part in the restoration of circulation, particularly in the vessels of the upper extremity. Secondary emboli or coexisting emboli at the time of operation contribute largely to the high mortality. Careful search should be made for other obstructive emboli or thrombi, above or below the primary embolus, before the incision in the artery is closed. Advanced arteriosclerotic changes do not necessarily contraindicate the operation, but the prognosis is not favorable even when the operation is done early. It is doubtful whether the operation is indicated or justified in patients who are suffering from a severe exacerbation of a subacute endocarditis and have a septic temperature, with a history of previous or associated embolic deposits. Embolectomy is the only definite surgical therapeutic measure known to the author at present for the relief of sudden circulatory obstruction by embolus.

Plasma Cell Granuloma in Nasal Carcinoma—Lederer and his associates report a case in which a rapidly growing anaplastic type of carcinoma apparently arising in the nares gave rise to retropharyngeal and cervical metastases. Secondary infection of the metastases to the lymph node resulted in a virulent septicemia. They observed that plasmocellular responses of tissue may accompany infiltrative processes. They may be local or systemic. The granulomas resulting from long continued sepsis are extremely confusing both in their clinical course and in their microscopic picture. This entity may be separated under the term of plasma cell granuloma. This response of the lymph nodes and tissues is usually the result of a generalized septicemia which may or may not be associated with a malignant condition. The clinical course is dependent entirely on the etiologic factor. Histologically, the tissues show a dense plasma cell infiltration or proliferation a marked and frequent bizarre response of the reticular cells and not infrequently as is common in chronic lymphadenitis, a more or less eosinophilic response.

Physical Therapy in Heart Disease E. Podolsky Brooklyn—p. 554

Splanchnic Stasis—Martin points out that treatment of splanchnic stasis is successful only by means of physical measures as drugs have practically no value. Vibration plays an important part in that it stimulates or inhibits the activity of the vasomotors. This modality is used far less often than its value merits, because few physicians are conversant with its great usefulness. The cord center controlling the splanchnic area is that between the second and sixth dorsal vertebrae. Vibration of this area for five minutes, with firm but not hard pressure, is a recognized part of the therapy. This should be given from above downward and from side to side, care being used not to override the vertebrae. In cases of marked myocardial insufficiency, vibration of the interspace of the seventh cervical and first dorsal for two minutes will add tone to the muscle, as shown by a slowed and stronger beat. In hypotensive cases vibration of the second cervical interspace will raise pressure through the sympathetics. Diathermy of the abdomen will do much toward restoring better circulation in that area. This may be given by the use of large metal electrodes for thirty minutes or longer, forty five or even sixty minutes being required in some instances. Following this, good results are obtained by the use of the Morse wave or the slow surging galvanic current. A well fitting support is

usually a part of the treatment, not only for the ptosis but also to assist in restoring the lost intra-abdominal pressure. The latter is an essential for circulatory restoration. Rest, proper exercise and food are necessary adjuncts.

Fractures of the Forearm—Mathews presents a simple and efficient method of handling difficult fractures of the forearm, which is carried out under general anesthesia. A small steel wire, 26 gage piano wire (001594 inch in diameter), is introduced through both the ulna and the radius, without previously incising the skin, half an inch below the styloid process by means of a specially constructed hand brace. The wire is started on the ulnar side, thus insuring passage of the wire through both bones. In a similar manner, wire of the same gage is inserted through the olecranon. With the wires in place alcoholic dressings are applied and held in place by a bandage. A U shaped compressible steel clamp is applied to both wires, and the arm is brought out to right angle abduction and flexed at the elbow. After the lower clamp is tied to a fixed object, overhead traction is applied. The traction frame consists of two pieces of one-fourth inch pipe, which are clamped across the table under the patient and extend out on each side of the abducted arm beyond the elbow. Each piece is provided with an upright member. Cross rods, which are bent at right angles, are slipped into both the upper and lower ends of the uprights and are fixed into position by set screws. The forearm is suspended between the under and overhanging cross rods. Traction can be exerted by raising the upper or lowering the lower cross rods and resetting the set screws. The fragments can be easily manipulated into position by means of a portable x-ray unit or lateral and anteroposterior roentgenograms. The bandages are cut and a plaster cast is applied from the midforearm down to the midpalm without disturbing the position of the arm. The wire pins are incorporated in the plaster, thus preventing the fragments from slipping. When the plaster becomes hard the clamps are removed and the protruding pieces of wire are cut off about one-fourth inch from the plaster and the ends covered. Immobilization is continued until there is a sufficient amount of bony callus to prevent a possible displacement of the fragments and, when roentgenograms show that the fragments will remain in place, the cast is removed, one end of each wire is cut close to the skin the wounds are cleansed, the wires are withdrawn and a new cast is applied.

Exposure to Ionized Air—Yaglou and his associates studied the influence of ionized air (small ions) on the total metabolism, respiration, pulse rate, blood pressure, body temperature and subjective sensations in human subjects lying on cots, (1) under basal conditions, (2) from two to four hours after breakfast and (3) from three to five hours after a light lunch. A group of sixty persons in a total of 141 experiments were exposed for a period of one hour or more to air containing from 5,000 to 1,500,000 ions per cubic centimeter after a preliminary resting period of from one to two hours in normal air. The results illustrate the special instances in which physiologic changes are possible and bring out the fact that under the conditions of the present experiments nothing definite was found to justify the use of artificial ionization in general ventilation.

*Stimulating Action of Copper on Erythropoiesis II B Stein and R C Lewis Denver—p 465

Action of Copper on Erythropoiesis—Stein and Lewis point out that the feeding of evaporated milk to normal rats produces a fall in hemoglobin without the corresponding drop in the erythrocyte count that occurs when raw milk is the sole article of diet. When copper without iron is fed as a supplement to raw milk, results similar to those with evaporated milk are obtained, indicating that the copper in the evaporated milk is responsible for the temporary maintenance of a high erythrocyte count. When given as a supplement to the milk diet of anemic rats, copper ranging in amounts of from 0.025 to 0.5 mg daily shows a definite erythropoietic action without any influence on hemoglobin formation.

*Carotid Sinus Reflex in Health and Disease Its Role in Crustation of Fainting and Convulsions Soma Weiss and J P Baker Boston—p 297

Carotid Sinus Reflex in Health and Disease—Weiss and Baker observed that mechanical stimulation of the carotid sinus produced either no fall in the systemic blood pressure or a fall of less than 10 mm of mercury in fifty normal subjects, while in forty-two patients having arterial hypertension and in thirty-six having primary arteriosclerosis without hypertension the fall in arterial pressure occurred more frequently.

and was of greater degree. In five cases with heart block, stimulation of the sinus was ineffective. Thirteen of fifteen patients in whom the carotid sinus reflex was hyperactive complained of spontaneous dizziness and fainting attacks, and pressure on one or each of the sinuses induced dizziness and fainting together with convulsive seizures. On mild stimulation the convulsive seizures developed contralaterally. A certain degree of quantitative correlation existed between the degree and duration of the pressure and the intensity of the response of the body. In four cases a sudden turn of the head induced dizziness and fainting. In six of the fifteen cases there was unequal dilatation of one or both sinuses; in three a small tumor pressing on the sinus was found and in the other six no gross abnormality was detected. These morphologic changes bear directly on the hyperactive state of the reflex but they are not the sole underlying cause of such hyperactivity, as cases with similar changes but without hyperactivity of the sinus were observed. The hyperactivity of the sinus is usually permanent but in two cases it was recurrent. Partial and complete heart block, temporary asystoles of the ventricle with continued auricular contraction nodal rhythm ventricular extrasystoles, changes in the shape of the T waves and complete inversion of the electrical axis in the heart were induced through the reflex stimulation of the heart. The authors' observations indicate that the Adams Stokes syndrome can be induced reflexly by stimulation of the hyperactive carotid sinus reflex. In the precipitation of such attacks local abnormality of the heart also plays a part. During stimulation of the hyperactive carotid sinus reflex the volume and the velocity of the flow of the blood become decreased. There is also a slowing of the flow of the blood through the brain. Ipmephrium abolishes the cardiovascular responses and the symptoms of the hyperactive reflex. Paralysis of the parasympathetic nerve endings with atropine abolishes the cardiac but not the peripheral vascular changes. In one case section of the intercarotid nerve abolished the spontaneous fainting attacks. The clinical symptoms and signs as well as the clinical changes are due to stimulation of the sinus and not to direct motor vagal stimulation. Cases of vertigo, dizziness, fainting and convulsions caused by a hyperactive carotid sinus reflex afford an opportunity to study the relationship between the systemic and cerebral circulation and these manifestations. The rate rather than the absolute deviation from the normal circulatory state of the brain plays the primary part in the precipitation of fainting and convulsions. A temporary sudden ischemia of even short duration sets up a sequence of events in the brain which then proceed independently to convulsions even if a hyperemia promptly follows the ischemia. Section of the carotid sinus nerve is advocated only in cases in which specific hyperactivity of the carotid sinus reflex exists.

Autogenous Vaccines in Treatment of Sinusitis—Cox has had twenty-eight patients suffering from chronic sinusitis, nasal allergy or asthma of the bacterial type under autogenous vaccine treatment. The patient was skin tested by injecting 0.05 cc of the various skin test emulsions intradermally in the inner surface of the forearm. Reactions were read in one hour and in twenty-four hours. The formation of a characteristic wheal or the formation of a red tender area 1.5 cm or more in diameter was considered a positive reaction. With the use of 0.05 cc of a 500,000,000 suspension the patient received approximately 25,000,000 organisms as a skin test dose. Emulsions of the organisms that gave positive skin tests were used in preparation of the autogenous vaccine. The individual emulsions were standardized at 1,000,000,000, through the use of a 0.25 per cent solution of phenosaline as a diluent and a 1,000,000,000 MacFarland standard. Equal portions of each of the emulsions were mixed in a 50 cc sterile vaccine bottle and tested aerobically and anaerobically for sterility. The initial

dose of vaccine was 0.05 cc, injected intracutaneously. Reactions were carefully noted and a subsequent increase or decrease of the dose made. Injections were given every fourth day, each dose being increased by 0.05 cc until 0.3 cc was given. Following this each dose was increased 0.1 cc and the injections were given subcutaneously. The maximal dose used was 1 cc. This dose was continued until examination revealed marked improvement in the mucous membranes of the structures involved, in addition to subjective improvement or until failure of the vaccine was indicated. Of the twenty-eight patients 71.4 per cent were so improved as to be classed as cured.

Relation of Trauma to Hernia—Moorhead states that hernia is never caused by injury; the preformed sac is always an antecedent. Hernia can be aggravated by injury if the source and symptoms are adequate. Immediate disabling pain is the chief symptom and this is associated with nausea, tenderness, swelling and other manifestations. At operation the observations usually denote an incipient process as indicated by extravascular and intravascular adhesions. The pathologic examination of the sac demonstrates chronic peritonitis and fibrosis. Hernia is a chronic progressive disease, a ptosis, a diverticulum and not an acute surgical entity except in rare instances. A large proportion of the adult male population have hernias and do not know it and surgeons do not know it either when treating them for contiguous injury grave enough to cause aggravation if trauma is regarded as a common aggravating factor. Like osteomyelitis, once a hernia always a hernia, and it is subject to periods of accession and remission.

Bone Marrow in Tularemia—Lillie and Francis state that focal lesions were almost constantly present in the bone marrow in acute tularemia of the five species of rodents in which the marrow was studied. They are frequent also in subacute tularemia in rabbits and guinea pigs. The focal lesions of the marrow often become granulomatous in character in subacute tularemia but also often remain as simple focal necroses while lesions in other organs are granulomatous. There is a greater tendency to granulomatous reaction in rabbits the subject of repeated inoculation with living cultures of *Pasteurella tularensis*.

but in some of these in which marked granulomatous reactions were present in the lungs a few days after the last inoculation, lesions are in all probability attributable to the inoculation made a month or more previously. Aside from focal lesions, there appears to be some destructive action affecting the more mature cell forms of the marrow. It appears probable that focal lesions may be encountered in the bone marrow of human cases when a more extensive search is made.

Wounds Sutured with Catgut and Silk—The experiments of Howes on rats demonstrate that in all the wounds repaired with silk, fibroplasia began earlier and the wounds accumulated strength more rapidly than in those sutured with catgut. Microscopic sections of these wounds showed the exudative phase to be of less duration in the wounds sutured with silk than in those sutured with catgut. The experiments showed that there was no advantage in using sutures of large dimensions—the larger sizes of silk or catgut gave no additional strength to the wounds either immediately after suturing or during healing. The author discusses the efficacy of catgut and silk as suture materials and the indications and contraindications for their use and states that by using catgut according to the silk technic the healing of wounds can be improved and untoward reactions reduced.

"Milk of Calcium" Bile—Schubbs and Goodstone present an unusual case of hydrops of the gallbladder which contained pure amorphous and crystalline calcium carbonate without stones but which was associated with cystic duct obstruction due to a stone of the same composition and was accompanied by a hypercalcemia. The roentgenologic studies revealed a shadow in the region of the gallbladder which shifted its position and changed its shape (crescentic and oval). The authors believe that the roentgen demonstration of such shadows is strong evidence in favor of a highly concentrated calcium sediment. They agree with Phemister that cystic duct obstruction is a constant factor that accompanies increased calcium content of the gallbladder. This factor is present whether the wall of the gallbladder is the seat of calcification or when the viscus contains pure calcium stones calcium soaps or as in the authors

case, pure calcium precipitate. While in Phemister's cases the cystic duct obstruction, when due to a stone, was always due to one of the cholesterol or cholesterol pigment variety, that in their case was caused by a friable calculus composed of the same material as that present in the gallbladder. It should be pointed out that in one of the cases reviewed by Phemister the obstruction was not calculous but carcinomatous in nature. The factors recognized as being necessary for stone formation, as laid down by Aschoff, were present in their case, and the authors believe that this is a type of stone formation. Some of the factors that are operative in their case, as in all cases of gallstone formation, particularly calcium stone formation, remain as yet unsolved.

Aseptic Uretero-Intestinal Anastomosis—Higgins describes a new technic, principally a modification of Coffey's transfixion suture method, for simultaneous bilateral transplantation of the ureters into the rectosigmoid in which the normal course of the urine and the continuity of the ureter are not interrupted until after the formation of a new channel between the ureter and the intestine. The operation is attended by no interruption of function in the kidney or the upper urinary tract until after communication between the ureter and intestine has been established. Peritonitis and acute renal infection are reduced to a minimum. The results in experimental animals have shown a lower mortality than that associated with other types of transplantation of the ureter into the intestine. The immediate results are most satisfactory, but sufficient time has not elapsed to warrant any statement as to the distant end-results. Anastomosis by this method performed on cadavers would seem to indicate its practical applicability for clinical use. The simplicity of the procedure and the lack of post-operative reaction have been most striking in contrast to the other types of transplantation. Evidence of back pressure on the kidney as indicated by hydronephrosis and also infection, is absent months after operation, owing to the maintenance of the valve-like mechanism of the intestine.

Low Back Pain—Hauser states that many cases of low back pain cannot be explained on the basis of organic changes in the back or as referred pains from disease in the pelvic or abdominal organs. They are due to a disturbance in function (functional insufficiency). The insufficiency is primarily in the muscles and is a condition in which apparently normal musculature is not equal to the demand placed on it. Proof that muscular insufficiency causes low back pain was obtained by the therapeutic test used in the author's fifty cases. This system of therapy was directed against the insufficiency and was used over a period of seven years. The treatment consisted in relieving the complaint, in correcting the deformity and in reestablishing strength. The course of treatment varied from five weeks to six months. Every patient showed a definite improvement. All those patients in whom normal strength was regained remained well.

*Unusual Case of Pneumonoconiosis G F Grisinger T R Bohm, and B Bradford Beckley—p 436

Pneumonoconiosis—Grisinger and his associates present a case of pneumonoconiosis in which there was apparent sudden onset and dense pulmonary fibrosis. Unlike the average case of silicosis, which over a long period of time presents symptoms of impending pulmonary disorder before the condition becomes actually manifest, this patient gives a history of good health with no symptoms pointing to the chest until nine months prior to the time the patient was admitted. This beginning illness was attributed to an acute cold. The authors state that it seems almost incredible that a person with such extensive and dense fibrosis and a pulmonary silica content of more than 50 per cent could go for fifteen months after exposure without some indication of pulmonary disturbance.

Cystic Oligodendrogliomas of Cerebrum—Greenfield and Robertson describe five cases of oligodendroglioma of the brain. Three were cystic tumors of the cerebral hemispheres and two were midline ventricular tumors. No age distinction can be made between laterally and medially placed tumors of this type. The former occurred in patients of from 16 to 61, and the latter in patients of 16 and 50 years of age. While a small medially placed tumor, by blocking the exit of cerebrospinal fluid from the ventricles may produce as severe symptoms as a larger laterally placed tumor, the great variation in the ages of the authors' patients is evidence that the tumors may begin to grow at any age period. The tendency to calcification in oligodendrogliomas bears little relationship to the age of the host. Calcified knots were found in the tumors in two patients of 16. In this series of cases they occurred in the stroma of the tumor and were not related to the walls of blood vessels or other connective tissue. The short preoperative histories and the rapid onset of urgent symptoms in the cases of laterally placed tumors were related to the expansion of cysts associated with slowly growing tumors. The rate of growth and the malignant condition of these tumors vary from case to case. Cases with ventricular and subarachnoid metastases have been reported and the authors describe further instances of both methods of spread. An oligodendroglioma growing in the wall of a cyst or in a cavity may alter its histologic appearances, assuming a more myxomatous type. Under these conditions of growth it is particularly liable to give rise to a mucinoid exudate, which may form large accumulations. The reticular appearance seen especially in paraffin sections appears to arise largely from shrinkage of this mucinoid material.

Syringomyelic Complications of Spina Bifida—Turnbull reports a case of cervical spina bifida in which signs suggesting a syringomyelic lesion of the cord developed in early adult life. Operation disclosed the stalk of a meningocele but no gross deformity of the spinal cord. Postmortem examination of the spinal cord showed (1) multiple small syringomyelic cavities, (2) fibrous tissue thickening of the parrachnoid and of the walls of blood vessels in the cord, (3) a stalk of functionless neural tissue extending from the dorsum of the cord into the lining of the meningeal protrusion and (4) a primitive ependymal tumor, which was of doubtful clinical significance.

Radiographic Appearances in Spondylolisthesis—Mitchell states that the crescentic shadow sometimes visible in anteroposterior roentgenograms of the lumbosacral junction is not pathognomonic of spondylolisthesis. In spondylolisthesis the bicristal is greater than the bitrochanteric length, a fact that is of diagnostic value, particularly when good lateral roentgenograms are not available. Ullmann's test is too delicate and occasionally may lead to a false diagnosis of early

spondylolisthesis. Defects of the interarticular neural arch cannot be demonstrated invariably at the present stage of roentgenographic technique. There is no characteristic position of the 1st lumbar spinous process in cases of spondylolisthesis. Diagnostic conclusions should not be based solely on comparisons of the anteroposterior lengths of the fourth and fifth lumbar vertebrae.

Diagnosis and Treatment of Syphilis—While watching *Spirochæta pallida* for days on end by the dark field method in the hope that he might obtain some clues about its morphology, Anwyll Davies was led to a new conception concerning the treatment of syphilis. He found that when the spirochetes are bathed in arsphenaminized serum they gradually lose their normal appearance, become ghostlike, fragmented and paralyze and in about five days apparently die. Then, in the space of five or six hours they recover their normal appearance, are revived, regain their spirals and motility, and become as normal and as active as control spirochetes that have not been similarly "doped." This strongly suggests that arsphenamine should be injected at intervals of five days or less instead of the customary week, which gives the spirochetes three days in which to recover. They should be attacked with fresh drug when their vitality is lowest. In this way the largest number of spirochetes are killed in minimum time, the survivors and resistant forms are destroyed sooner and what is equally important, they are prevented from multiplying and are less likely to develop resistance to arsenic. On this basis the author started a strong biweekly course of injections three years ago. For the first five weeks 0.45 Gm. of neoarsphenamine and 0.2 Gm. of a bismuth compound were given intravenously once a week, and also in the middle of the week 0.3 Gm. of sulpharsphenamine and 0.2 Gm. of a bismuth compound subcutaneously. For the next three weeks a mixture of potassium iodide was given, and then a repetition of the treatment of the first five weeks. A blood test is made in seven days and again in twenty-eight. A mixture of potassium iodide is given in the interval (eight weeks) before the next course. The Wassermann reaction was 100 per cent negative a month after the first course in sixty-five primarily seronegative cases, 93 per cent negative in 114 primarily seropositive cases and 95.1 per cent negative in sixty-two secondarily seropositive cases.

Test for Tribrom-Ethanol Solution—Ashworth describes experiments which prove that "universal indicator" is a more sensitive and reliable agent than congo red as a test for the purity of solution of tribrom ethanol. The universal indicator is prepared by dissolving 0.04 Gm. of methyl orange, 0.02 Gm. of methyl red, 0.18 Gm. of naphtholphthalein and 0.08 Gm. of phenolphthalein in 100 cc. of a 70 per cent solution of alcohol (the Extra Pharmacopeia). In testing the purity of tribrom ethanol, he transfers 3 mg. of prepared solution of tribrom ethanol to a test tube and cools it. In a similar test tube he places an equal volume of the distilled water used in the preparation of the solution of tribrom ethanol and adds 2 drops of the universal indicator to the contents of each tube. The solution should be greenish yellow and it should not be possible to detect any difference in the color of the contents of the two tubes. The test tubes should be scrupulously clean and

previously rinsed with distilled water. The pH of ordinary distilled water may vary and the actual sample previously used for the preparation of the solution should serve as the control in the test. In the presence of alkaline solutions (pH 8) the universal indicator gives a green color, in neutral solutions (pH 7 or 7.5), greenish yellow, in acid solutions respectively pH 6.5, 6, 5.5 and 4, yellow, orange-yellow, orange and red.

Treatment of Acute Tetanus—Lovelock-Jones reports a case of acute tetanus in which recovery followed large doses of antitetanus serum administered subcutaneously intrathecally and intravenously. Further local excision of the wound was undertaken and eusol (highly oxygenating) dressings were kept applied. Magnesium sulphate was administered intrathecally and phenol subcutaneously. Antipneumococcus serum also appeared to help when a bronchopneumonia threatened. The case illustrates the fact that diminution or stoppage of the serum brings on fresh spasms or increases the rigidity which subsides promptly on the administration of more serum. In all, approximately 1,800,000 units of antitetanus serum was used in this case.

Localized Outbreak of Enteritis Due to *Bacillus Dysenteriae* (Sonne) Margaret E. R. Loudon—p. 100

Outbreak of Enteritis—Loudon reports an instance of a localized (one family) outbreak of enteritis in which in the eldest daughter and the parents there were no clinical symptoms. The source of infection remains obscure. The mother cooked for all members of the family, but she had no symptoms at any time, although her blood serum agglutinated *Bacillus dysenteriae* (Sonne) to a titer of 1:960. The first member of the family to be affected developed a rapidly fatal infection. In most of the others the attack was of a moderate or mild type, and in some there was only serologic evidence of the infection. Two members of the family, one with no clinical symptoms, the other with a mild attack, developed acute appendicitis two months after the discovery of the infection and within five days of each other. Both had a high concentration of specific agglutinins to *B. dysenteriae* (Sonne) in their blood at the time of operation. The appendices were not examined bacteriologically.

*Conduct and Value of Schick Testing and Active Immunization Against Diphtheria During an Outbreak C. S. Barbour—p. 363

Points in Practical Application of Diphtheria Control Measures M. J. Holmes—p. 366

Diabetes in Childhood E. Downie—p. 367

Perennial Treatment of Hay Fever C. Sutherland—p. 373

Immunization Against Diphtheria—Barbour proves the value of an active immunization campaign during an epidemic by quoting cases in which the development of clinical diphtheria was prevented. Partial proof was obtained in other cases and the inference could safely be made for many others. The immunizations were performed from July to October, by which time the outbreak appeared to have subsided. A further thirty-nine cases had occurred, totaling eighty which spread over from April to October. A campaign conducted during an outbreak of diphtheria will receive a ready response from the public, in contrast to the apathy shown in interepidemic periods. It is possible to dispense with a control for the Schick test if time is a factor. And if the matter is urgent, as about 50 per cent of any group of children of mixed ages may be expected to be susceptible, it would seem that the Schick test could be dispensed with altogether, the added risk involved in injecting immune children being balanced by the quicker development of immunity in the susceptible children. The disadvantage of mass Schick testing is the time absorbed in performing and reading the tests. The full injections of anatoxin confer

absolute immunity (absolute on Schick test standard) in 90 per cent of cases and an increased immunity in 10 per cent (since the Schick test can be read quantitatively to a certain extent). Even small doses cause the development of some active immunity, but it is not until the first decimal place is reached (0.1, 0.2) that the immunity is appreciable with only two injections. Anatoxin is to be expected to give no general reaction and no local reaction of serious import if the dosage is regulated by the previous skin test. In young children, in whom immunization is most desirable, anatoxin sensitiveness is exceptional.

*New Method of Roentgenotherapy in Treatment of Leukemias Total

Teleroentgen Therapy G. Marchal and L. Mallet—p. 730

Gastro Intestinal Malformations in a New Born Infant H. Roueche—p. 734

Roentgenotherapy in Treatment of Leukemias—Marchal and Mallet have employed total teleroentgen therapy with favorable results in three cases of monocytic leukemia, two cases of lymphatic leukemia, and one case of myeloid leukemia. The principle of this method consists in irradiating at one sitting, the entire organism, or at least large fields, with weak and penetrating doses of roentgen rays, two or three times a week. The chief advantage of this method is that with low doses, about one twentieth of the erythema dose (at the end of a series), it achieves results comparable to those produced by the classic method in regard to general condition, regression of the hypertrophy of the hematopoietic organs and modification of the blood picture. It is harmless for the skin and permits better control of the erythrocyte formula. The relative innocuousness of correctly dosed teleroentgen therapy permits the frequent repetition of follow-up treatments without fear of development of roentgen resistance. The authors have observed no roentgen resistance and none of the injurious effects sometimes following the classic treatment, such as leukopenia, acute attacks of leukemia, or severe anemia. In teleroentgen therapy the manifestation of the clinical and hematologic effects is delayed for from two to five weeks at the outset of treatment, but after this period it is proportional to the number of irradiations and continues after their discontinuation. In acute cases this period of latency may appear as an obstacle to the method. For the initial treatment of all forms of chronic leukemia the authors recommend total teleroentgen irradiation for from five weeks to three months, supplemented by local irradiation in case of inadequate improvement. For the treatment of recurrences they recommend total irradiations for from three weeks to three months. For follow-up treatment irradiation series of from two to four weeks at intervals of from one to three months are recommended. Teleroentgen therapy is also indicated for beginning or recurrent leukemias with a minimum of clinical and hematologic signs, and for forms that are resistant to local irradiation.

*Oxaluria and Infestation with Intestinal Parasites V. Giudiceandrea—p. 1755

Hemorrhagic Necrosis of Pancreas Pseudocystic Type of Korte G. Trogu—p. 1758

Poisoning Due to Fungi A. Filippini—p. 1762

Oxaluria and Infestation with Intestinal Parasites—Giudiceandrea states that examination of the feces of patients with oxaluria sometimes reveals the presence of parasites in the intestine. The author studied a group of patients suffering from intestinal infestation with *Amoeba histolytica*, *Endolimax nana*, *Tricocephalus*, *Lambia intestinalis*, *Amoeba coli*, *Chylomastix* and other parasites. Treatment resulted in a diminution or the complete disappearance of the oxaluria. In one case of infestation with *Tricocephalus*, the author found both eosinophilia and oxaluria. He thinks that these parasites bring about certain organic alterations of the intestinal flora leading to a relative toxic condition of the liver acting on the metabolism. He maintains that oxaluria may also occur as a primary alteration of metabolism as well as in the course of various diseases such as gastric hyperchlorhydria.

Lambliasis of Liver and Bile Passages.—Gorn and Sprachez point out that *Lambli* intestinalis causes not only simple intestinal disturbances with acute and chronic diarrhea but also conditions that resemble dysentery or cholera. Moreover, in recent times many investigators have expressed the opinion that this parasite may be the cause of disturbances in the biliary tract. The authors mention the factors that have been cited in support of this theory and showing that many others are opposed to this theory they deny the etiologic role of *Lambliasis* in disturbances of the liver and of the bile passages. They relate their own observations which they summarize as follows. *Lambli* intestinalis is found primarily in the duodenum. It may wander into the bile passages but it stays there for only a short time and the gallbladder certainly is not a reservoir for the parasites, as believed by some. Even in cases in which the parasite enters the bile passages it does not cause lesions in the liver and the biliary tract and observations on angiocholitis, cholecystitis and pericholecystitis are only symptomatic for they never could be corroborated anatomically. Formerly the diagnosis of cholecystitis or angiocholitis was nearly always based on the fact that the parasite was demonstrated in the bile according to the method of Meltzer-Lyon. However, the presence of the parasites in the B bile is an accident and is due to the irritating action of magnesium sulphate which loosens the *Lambli* from the intestinal mucous membrane. Because of this the *Lambli* is found in larger numbers in the feces following administration of magnesium sulphate. Thus magnesium sulphate can be given for diagnostic purposes, particularly in cases that are not suited for duodenal probing. The fact that infestation with *Lambli* intestinalis is so frequently accompanied by manifestations on the part of the liver or the bile passages makes it appear probable that the parasite causes them indirectly by promoting the infection of the biliary tract. Moreover it is possible that the toxins of the *Lambli* play a part by impairing the liver or by producing systemic disorders, such as anemia, intestinal disturbances, vertigo and headaches.

Motility and Secretion of Stomach in Acute Gastritis.—Kaden studied the motility and the secretory function of the stomach in twenty-four patients with acute gastritis. The symptoms lasted from three to twelve days. Two patients had an alcohol gastritis, in eight the disturbance was the result of a mistake in the diet, in three an oxalic acid poisoning existed, and in eleven the etiology of the gastritis could not be determined. The symptoms were more or less the same in all twenty-four cases. Vomiting and headaches were present in nearly all patients, and some complained of nausea, weakness and lack of appetite. Some had an aversion to all foods while others rejected only sweets. Several patients complained of eructation. Abdominal pains, thirst and a feeling of heat were frequent complaints, but actual fever was present in only three of the patients. In many of the patients a leukocytosis was detectable, even when there was no increase in temperature. Studies on the motility, which were made from twelve to twenty-four hours after the noxious influence had acted on the stomach, revealed that it was accelerated, for the discoloration of the test solution was accomplished in a shorter time. The secretory conditions indicated an increased irritability of the glandular apparatus. Not only the quantity of the gastric juice was increased but also its acidity. The glandular apparatus responded more readily to stimuli. Signs of inflammatory changes were also present in the sediments of the specimens withdrawn from the stomach, for they contained an increased

number of leukocytes and epithelial cells. Another sign of inflammation was the increased lactic acid content of the stomach.

Intracutaneous Injection of Gastric Juice.—In studies on syphilitic gastritis, Weidinger found that it is difficult to differentiate this type from other forms. He decided to make the late reaction following the intracutaneous injection of the gastric secretion the subject of his investigations, in the hope of finding a means to differentiate syphilitic gastritis from gastritis of different origins. The gastric juice was withdrawn from the fasting stomach and 0.1 cc. was injected into the skin of the upper arm. A reaction was manifest after from one to two minutes, but in watching the late reactions it was found advantageous to take as a basis the reaction that is visible after twenty-four hours. The estimation of the reaction was based on the diameter of the wheal, the sharpness of its outline, the intensity of pigmentation and the degree of infiltration. The test was made on 170 patients and undesirable complications were never observed. As control tests, injection of liver extracts from animals, lentin or solutions of lecithin, cholesterol, hydrochloric acid or pepsin were given. The latter reaction quite frequently corresponded to the reaction obtained with the gastric juice. The latter gave positive reactions most frequently in persons who had had syphilis or malaria, but the author considers it wrong to diagnose a syphilitic gastritis on the basis of the intracutaneous reaction. In patients with hyperacidity the vaccination with gastric juice frequently had a therapeutic effect for the patients often reported that their symptoms had decreased after the injection. The improvement thus obtained was permanent in about twenty-five patients.

Treatment of Lupus Vulgaris with Borderline Rays and Diet.—Schreus and Engelhardt report their experience with borderline rays in the treatment of patients with lupus vulgaris, most of whom were receiving the salt-free diet recommended by Sauerbruch, Herrmannsdorfer and Gerson. The irradiations were given with 9 kilovolts and 0.02 cm. of aluminum which absorbs half the rays. The treatment was always local. The lupus was irradiated in such a manner that from 0.5 to 1 cm. of the surrounding normal skin was also exposed to the rays. The single dose never exceeded 1,500 roentgens. The dose should be large enough for a noticeable erythema and a slight swelling to become manifest in from three to eight days. If the reaction does not develop until after this time, the dose was too small and a larger one has to be given the next time. The erythema persists for from one to three weeks and a new irradiation is not given until the erythema has disappeared at the earliest after ten days. In many cases an improvement may be noticed after the first erythema has disappeared, but in many others, from 5,000 to 6,000 roentgens, that is, from three to four irradiations, are necessary. The authors gained the impression that patients who received the salt-free diet reacted to the irradiations better and quicker than did those who were not subjected to this diet but, even when employed alone, the borderline rays may produce a cure. The irradiations with borderline rays are more effective than those with the quartz lamp and yet the reactions are much milder. The treatment with borderline rays requires more time than, for instance, the treatment with the diathermy loop but it has the advantage that it can be made ambulatory, as the reactions produced by the irradiations are not sufficiently severe to necessitate the cessation of employment. The authors warn against too early cessation of irradiations. They think that many failures are due to the fact that the treatment is discontinued because the first irradiations do not seem sufficiently effective. The total dosage is as a rule from 6,000 to 8,000 roentgens. The authors were able to produce a complete cure even in a case of Boeck's sarcoid. Because of a comparatively small material, they are

unable to give definite percentages of cures effected with borderline rays in lupus vulgaris, but they think that a trial is always justified, for impairments were never observed

Gonococcus-Like Bacteria in Genital Tract—In order to determine what bacteria occurring in the genital tract are most readily mistaken for gonococci, Schubert and Beck made cultures of the genital secretions of seventy patients which on microscopic examination had revealed gram negative, gonococcus like forms of bacteria. In studying the cultures, the authors found that the staphylococci and streptococci which in the original smear appeared gram negative, are the most frequent source of error, but that coccibacillary forms of the colon bacillus and *Proteus bacillus* likewise may be mistaken for gonococci. In four of the seventy cases in which on the basis of microscopy of the smear, gonorrhea could only be suspected, the culture permitted the definite diagnosis of gonorrhea.

Amines in Intestine of Nurslings—Brandes was able to corroborate the observations of Rominger and Meyer, who found that the stools of nurslings fed on the bottle contain larger amounts of amines than do those of breast-fed infants. She further points out that Rothler demonstrated the presence of amines in the urine of nurslings presenting toxicosis and that he concluded from this that toxicosis of nurslings is an amine poisoning. This, however she does not accept, for she shows that amines may form in the urine in the course of its passage through the urinary tract and that consequently the demonstration of amine in the urine is not necessarily a proof that the toxicosis is the result of an amine poisoning.

Experiments with Short Wave Diathermy—Kowarschik has tested apparatus for short wave diathermy the use of which has been recommended because of the following advantages: 1 There is no danger of burns because the electrodes are covered with rubber or with some other substance. 2 The application is simple since the electrodes can be applied over the clothing. 3 The penetrative power of the heat is better and more uniform. The author relates physical experiments and experiments on the cadaver and sums up his observations as follows: 1 In short wave diathermy it is immaterial whether the various resistances in the circuit are connected in series or in parallel. The heating takes place according to Joule's law that is, it is dependent only on the electrophysical behavior of the resistance (conductivity and dielectric constant). 2 It is incorrect to assume that the short wave diathermy as heretofore practiced with the aid of condenser electrodes the dielectric of which consists of hard rubber soft rubber or felt gives a relatively better penetration. On the contrary the heating conditions in ordinary diathermy are much more favorable in the

therapeutic application. The conditions are extremely unfavorable if the electrodes, instead of on the skin, are applied over the clothing. 3 The type of dielectric of the electrode plays an essential part in the homogeneity of the heating. 4 If uncovered metal electrodes are employed for the short wave diathermy, the penetration is somewhat superior to that of ordinary diathermy. 5 However, the superiority of short wave diathermy becomes manifest in its entirety only if according to the method of Schliephake, the treatment is done in the air condenser field. 6 The caloric output of the apparatus for short wave diathermy, when compared to that of the ordinary diathermy apparatus is extremely small. If the apparatus of short wave diathermy is used with air condenser electrodes (the only application in which short wave diathermy shows itself superior to ordinary diathermy) the caloric output is still inadequate.

Erythema Threshold in Irradiations with Ultraviolet Rays—In discussing the difficulties encountered in the therapeutic application of ultraviolet rays, Wucherpfennig emphasizes (1) the fluctuations in ray sensitivity due to miring by previous irradiations and (2) the lack of a reliable instrument for the physical measurement of the quantities of rays. Most of the instruments so far devised are dependent on the wavelength of that particular type of lamp for which they were gaged that is, they are suitable for that individual lamp but not for lamps of different spectrums. The author mentions the various biologic reactions that may serve as indicators for the intensity of the ultraviolet rays but he thinks that only the erythema effect is sufficiently understood in its dependence on the wavelength as well as in regard to its other biologic factors to be a suitable test reaction. He discusses the erythema threshold which he defines as 'that quantity of ultraviolet rays which is just sufficient to permit the demarcation of an irradiated field on the upper part of the back, seven hours after exposure. This erythema must have been produced by a quantity of rays which is 20 per cent larger than the amount applied to the neighboring field that is just under the threshold of visibility.' The most difficult but also the most essential factor in the determination of the erythema threshold is the gradation of the ray stimuli, so that the next field always receives 20 per cent more than the preceding one. This difficulty was solved by the author, in collaboration with Mathiesen, by an instrument the so called sector stars which makes use of the sensometer disk. The ground plate of the apparatus has a rectangular cut-out of 9 by 55 mm, which by strips of 15 mm is subdivided into eight fields, each measuring 6 by 9 mm. A sector disk rotates above this cut-out and has notches arranged in such a manner that each succeeding field has a ray exposure which is 20 per cent in excess of the preceding one, the respective percentages being 100, 83, 69, 58, 48, 40, 33 and 28. The threshold time can be determined seven hours after the test by multiplying the field showing the erythema threshold with its corresponding factor (1.0, 0.83, 0.69 or any of the others). The author asserts that this test method makes it possible to administer to any person ray treatments that are biologically equivalent, irrespective of the sensitivity of the person at the time of the treatment or of the spectrum of the ultraviolet source.

Tubercle Bacilli in Blood in Chorea—Loewenstein reports two cases of chorea in which tubercle bacilli were obtained in pure culture from the cerebrospinal fluid. In one patient a boy aged 11, in whom the chorea apparently had existed for about a year tubercle bacilli were found only in the cerebrospinal fluid, while the blood culture remained nega-

tive. In the other patient, a girl, aged 9, the chorea was of recent development, and in this case both the blood and the cerebrospinal fluid gave positive cultures of tubercle bacilli. A postscript mentions two other cases of chorea in which tubercle bacilli were detected in the cerebrospinal fluid and in one of which the blood culture likewise was positive.

Acetylcholine Chloride in Treatment of Arteriosclerosis.—Marl ovits studied the influence exerted by acetylcholine chloride on the blood pressure and on the symptoms of arteriosclerosis. He tried the subcutaneous, intramuscular and intravenous injection of the aqueous solution of acetylcholine chloride and found that for subcutaneous administration from 0.02 to 0.05 Gm was sufficient. In intravenous injection the same results could be obtained with from 0.01 to 0.02 Gm. The optimal intramuscular dose was between 0.05 and 0.15 Gm. Oral administration of 0.2 Gm had no effect whatever. The intramuscular injections were found to give the most satisfactory results. Undesirable secondary effects were never observed. Daily injection continued for from ten to fifteen days effected a slight decrease in the blood pressure and the spastic symptoms in the extremities improved. However two weeks after the termination of the treatment the blood pressure reached its former level again but the symptoms in the extremities returned only partially. A continuation of the injections effected no further improvement. Two patients with intermittent claudication were cured. The treatment was ineffective in a patient suffering from apoplexy. Four patients presenting torticollis, headaches, vertigo and tinnitus were temporarily improved but several weeks later most of the symptoms reappeared. Essential and menopausal hypertension and the headaches and prims in the extremities occurring in patients having nephrosclerosis were improved for shorter or longer periods (up to four months). The author thinks that the decrease in blood pressure is the result of a vasodilatation. He expresses the opinion that choline preparations may be given with success in the incipient stages of hypertension.

- *Five Years' Experiences with Rectal Tribrom Ethanol Anesthesia. A. Schulte—p. 2565

Hormonic Causes of Habitual Abortion.—Mayer admits that in many instances habitual abortion may be the result of such disorders as genital hypoplasia, retroflexion of the uterus, nephritis, syphilis and deficiencies of the iron, calcium and phosphorus supplies or of the growth vitamins. However there are many cases in which the causes cannot be found and in such cases the possibility of hormonal causes should be considered. The hormonal factors that play a part in the normal development of pregnancy are impulses from the corpus luteum on the uterus, the reaction capacity of the uterus to these impulses and the normal vitality and aggressiveness of the ovum. Disturbances in these factors may lead to abortion by causing the intra-uterine death of the ovum or by stimulating labor pains prematurely. The author discusses the functions of the corpus luteum and the deficiencies in these functions, the vitality of the ovum, paternal influences, the role of blood groups, thyroid influences, and the relation between abortion and the sex of the fetus. In discussing the treatment of habitual abortion, he states that since the premature onset of uterine contractions may be caused by a lack of corpus luteum hormone administration of corpus luteum extract may be helpful. On the other hand, it may be assumed that the serum of normal pregnant women contains a substance that inhibits uterine contractions, and for this reason it has been suggested that women who are subject to habitual abortion might be treated with the serum from healthy pregnant women. This is the more justified in

view of the fact that this procedure has proved helpful also in certain toxicoses of pregnancy. Moreover, it is possible that the serum of healthy pregnant women contains a substance that has a growth promoting influence, that through hormone influences it makes certain substances of the maternal organism more readily available to the fetus or that it is capable of combining with certain fetocidal toxins of pregnancy and thus preventing the death of the fetus by toxic influences. The author realizes that much of this is still theory, but he thinks that these factors should be considered.

Experiences with Tribrom-Ethanol Anesthesia.—Schulte employed tribrom-ethanol anesthesia in 1216 gynecologic operations. A table lists the following interventions: is having been performed under tribrom-ethanol anesthesia: intefixation of the uterus alone or in connection with operations on the adnexa or with appendectomy, supravaginal amputations, abdominal and vaginal total extirpations, Wertheim's radical operations, exploratory laparotomies, minor gynecologic interventions, cesarean sections and other interventions. In over 50 per cent of the cases tribrom ethanol effected a complete or nearly complete anesthesia while in the others some ether had to be given. In slight complications that may arise, oxygen inhalation is generally sufficient but cardiac stimulants should be kept on hand and the blood pressure should be controlled. Tribrom ethanol anesthesia failed completely in eight cases: that is the patients reacted to the anesthetic slightly or not at all. Three patients died during or after the operation but the author shows that these fatalities were probably caused by the extremely weakened condition of the patients rather than by the anesthetic. His general conclusion is that tribrom-ethanol anesthesia compares favorably with other types. He points out that literature reports indicate that tribrom-ethanol anesthesia is now used in nearly all fields. He stresses as its main advantages the simplicity of its application, the elimination of the period of excitation, the complete retrograde amnesia and the absence of postoperative pulmonary complications.

Osteopsathyrosis and Syphilis.—Mikulowski presents a case of fragility of the long bones and syphilis in an infant of 9 months born of a syphilitic mother. Previous treatment for curvature was not beneficial. Besides syphilis the child suffered from general acute anemia with an enlarged spleen. In spite of antisyphilitic treatment there was no improvement and roentgenograms showed no beneficial change in the condition of the bones. A general plaster cast was applied in suspension, so that the child remained immovable for five weeks. During this time the patient was given 0.01 Gm of mercurous chloride, 0.03 Gm of acetarsone and potassium iodide and then six injections of 0.12 Gm of neosphenamine at intervals of six days. The anemia contraindicated the administration of bismuth compounds. General treatment consisted of opotherapy in the form of parathyroid and thyroid serum lozenges, or a 1 per cent solution of viosterol (sterogyl) and then viosterol in oil (vigantol). The child received thirty irradiations with the quartz lamp and was discharged from the hospital after three months in good condition.

TYPES OF NEPHRITIS AND THEIR MANAGEMENT

HENRY A. CHRISTIAN, M.D.
BOSTON

There are numerous clinical classifications of nephritis or Bright's disease. Each author seems to have suggested a different classification with a resultant complexity of nomenclature that often proves confusing to both student and practitioner. However if the various classifications are studied in relation to the author's ideas about the disease it becomes apparent that the differences are more a matter of words than of concept. If one tabulates a number of classifications and rearranges them, as I have recently done for a chapter on nephritis in a new edition of Cecil's textbook of medicine, it is evident that a few fairly simple concepts underlie all of these classifications.

All classifications take into consideration a concept of time or duration and so there are acute, subacute and chronic types of nephritis. Of these subacute is the one less definitely demarcated, being at times a name for a type that is, in all respects, similar to acute nephritis except for an unduly long persistence of evidences of the disturbance, and at other times denoting a patient whose symptoms and physical signs are those of chronic nephritis and yet they have developed and progressed so rapidly as scarcely to be rightly termed chronic in the sense of time. If these differences are kept in mind, nephritic patients can be grouped into two major classes, acute and chronic without much if any, lessened utility from the classification as a result of omitting the term subacute.

From the point of view of pathologic change as well as from that of symptomatology, nephritis may be divided into two great groups, one in which the lesion predominately concerns the glomeruli and the other in which the vascular system of the kidney shows the essential changes. Clinically, acute forms are not recognized in the latter type.

The application of these two concepts, as shown in the accompanying appended tabulation of different classifications, gives one group of acute nephritis and two groups of chronic nephritis whatever terminology is used. Within these three major groups varying degrees of subdividing may be carried out according to the taste of the classifier in expressing in his classifications clinical subdivisions which he believes will be helpful in either a better understanding of the disease or a more satisfactory clinical management of the patients.

Clinically, urinary observations, edema, increase in blood pressure and nonprotein nitrogen retention with eventual uremia are the four significant departures from

normal whose absence or presence in varying degrees determines the type of nephritis and its place in any of the classifications. Of these, all except the determination of nonprotein nitrogen values in the blood have been followed in the study of nephritis since Bright in his classic publication of 1827 described them, except that only the results of increased blood pressure could be noted until comparatively recently, when clinical methods of measuring blood pressure were inaugurated by Riva Rocci. Bright even recognized the low plasma protein of certain cases of nephritis and, of course, was familiar with the clinical manifestations of uremia, which in a way is the result of nonprotein nitrogen retention. In other words, classifications still in very large measure are based on simple methods of study available almost from the beginning of any systematic recorded knowledge of nephritis. What is recent in knowledge of the pathology of the condition is knowledge of the finer histologic changes in the kidney, and this is not very recent. Bright's descriptions of the gross pathology scarcely have been improved on.

In the history of the study of nephritis two fundamental concepts of its pathology have prevailed, one supporting a unity of process, the other opposed to this unity. Pathologists at one period regarded all forms of nephritis as only stages in a single type of lesion, the appearance of the kidney at death depending on the severity and the duration of the pathologic process. This idea however, was given up as not satisfactorily explaining the variety of kidney lesions encountered on postmortem examination, and a conception of the lesions on a dual or even multiple basis was advanced, a dual basis seems today better to fit with the combined clinical and pathologic knowledge of nephritis than a belief in a greater multiplicity of types of lesion.

The present concept of a duality of lesion places very little primary importance on changes in the tubules except for those who regard so-called nephrosis primarily as a form of tubular degeneration, a view not held by a large number of investigators. However changes coming about secondarily in the epithelium of the tubules do influence renal function in some degree in all forms of nephritis.

As already stated the dominant lesion in one group of nephritis patients lies in the glomerulus, in the other in the vascular system. Obviously, the glomerulus is a vascular unit, though one modified in that in the glomerulus the capillary has in addition to the usual structures a further layer made up of greatly flattened epithelial cells derived from the tubule. In final analysis, it is the presence of this layer derived from the epithelium of the tubules and changes in it that have much to do in determining a subdivision of nephritis into two distinctive groups.

In the architecture of the kidney, the capillaries surrounding the tubules contain blood that has previously

passed through the capillary tuft of the glomerulus. Hence nutrition for the tubules and any function of the cells lining the tubules are influenced by vascular lesions either of the glomerulus or elsewhere in the renal vascular tree. Similarly, a vascular lesion on the cardiac side of the glomerulus or one within the glomerulus equally may influence function of the tubules as well as function of the glomerulus. Consequently a given disturbance in renal function may be referable to a lesion either predominantly of or before (that is, on the car-

fact that furnished support for the idea, once held, that all forms of nephritis were but varying stages in a single pathologic process.

Turning now to clinical evidence, there is support here, too, for the idea of duality of lesion. There seems definitely a form of nephritis that follows infections, such as infection of the respiratory tract, and another type in which infection plays no demonstrable role but in which vascular degenerative lesions, whatever their cause may be, are causative of disturbance of renal

diac side of) the glomerulus, and changes observed in the function of the glomeruli may result from lesions either primary within the glomerulus itself or secondary to some disturbance of the vascular tree bringing blood to the glomeruli.

In either of these two types of renal lesion, as time goes on, epithelial elements of the tubule atrophy and interstitial tissue proliferates. If in the beginning the general vascular tree is normal, as these atrophic changes appear the blood vessels undergo changes in their caliber and in their wall, so that eventually the chronic renal lesion of great duration is not very different, whatever type it was in the beginning. It is this

function. In the first type both acute and chronic stages are observed, while in the second type no clinical evidence develops until the vascular lesion has become chronic. Almost nothing is known about the earlier stages of the latter either clinically or pathologically. What is confusing in making this differentiation is the existence of cases which from a stage of acute nephritis, sometimes not recognized, apparently go on to recovery, though actually the lesion has remained latent and continues latent for a very long period, eventually to cause the disturbances in renal function usually associated with chronic vascular lesions, although the lesion dominantly from the beginning has been a slowly pro-

gressing glomerular lesion with secondary changes in the vascular tree, atrophy of renal excretory structures and proliferation of interstitial connective tissue, the secondarily contracted kidney of many authors.

Lack of information of the exact role of the infecting agent, most frequently some type of streptococcus in the mechanism of the production of lesions of the glomerulus and lack of information of both etiology and mechanism of so-called degenerative vascular lesions, have retarded so far an understanding of nephritis in its various manifestations and prevented a more generally accepted classification of nephritis and perhaps prevented the development of more efficient methods for the management of patients with nephritis.

From the point of view of management the prevention of nephritis is extremely unsatisfactory. As far as acute nephritis and the glomerular type of chronic nephritis are concerned, all that can be done is to prevent so far as possible, and to treat as thoroughly as possible, all acute infections especially those of streptococcal cause. Closely allied is the prophylaxis of the common cold and its sequelae. For all of this there are no specific measures, except to a certain extent for scarlet fever, and, when all is done and said, the medical profession is quite powerless to prevent the development of this type of nephritis. As for the vascular form, even less is known as to the cause and practically nothing as to prevention can be accomplished. Preventive medicine is much talked about at present but can actually accomplish practically nothing so far as chronic disease of all sorts is concerned. This certainly is true for chronic nephritis of any type.

Ideas as to the management of a developed nephritis of any type have been considerably modified in recent years. We recognize that the disease by no means is limited to the kidney. Now practitioners are more influenced in their plan of treatment by consideration of the patient as a whole than in the past, now they consider less dietary constituents that theoretically increase the work of the kidney and are more concerned with maintaining the nutrition of the patient at a high level. The use of a high caloric diet in prolonged fevers, such as typhoid, has taught the benefits and shown the absence of harm from such diets and has been an important influence in greatly liberalizing the dietary management of the nephritic patient of any type. Only in the early days of a very acute nephritis should diet be restricted in both amount and variety. For a week in such cases a diet of fruit juices and carbohydrates with restricted fluids is advisable. Then rapidly the diet should be expanded to one essentially adequate in amount and variety with only moderate restriction of protein, salt and fluid, a diet not very different actually from a normal diet, free from any excesses, of most Americans.

Since infection has an etiologic relationship to acute nephritis, infection should be treated as adequately as possible and due consideration should be given to the eradication of real foci of infection. The indiscriminate removal of teeth and tonsils in such patients is to be deprecated.

In acute nephritis there is practically no indication for drug medication. Edema rarely is marked in degree and only then should diuretics be used. If used, their employment should be restricted and the amount given be governed by whether or not a diuresis ensues. As a rule, diuretics are not to be used.

Sweating no longer is considered advisable, this really applies in all forms of nephritis. Exposure to

cold and wet should be guarded against. However, with proper clothing, change of climate is not a necessity in any part of the United States. A developing uremia may be managed as described later on in connection with chronic nephritis. Fortunately, it is rare to any marked degree in acute nephritis. The circulation in acute nephritis is not sufficiently disturbed to indicate any therapeutic procedures. A patient with acute nephritis should remain in bed at complete rest so long as there are indications of gradual clearing of the activity of renal process, blood in the urinary sediment is the best index of this. If, after prolonged rest, no change in activity of process occurs, physical activity should be permitted in increasing amount, provided it does not cause increase in blood cells in the urine.

Chronic nephritis of all sorts is first of all a chronic disease. This means a long period of management and necessitates a continued entirely adequate diet, adequate both as to food constituents and as to caloric requirement for the activity allowed to the patient. Only with a rising value of blood nitrogen is there any reason for marked dietary restriction. In patients with chronic nephritis, four factors influence the therapeutic and dietary management. These are edema, nitrogen retention with the possibility of uremia, anemia, and circulatory failure associated with hypertension.

Edema in nephritic patients is of two types, renal and cardiac or circulatory. Renal edema occurs in patients excreting large amounts of albumin who are not anemic, have no evidences of disturbed cardio-circulatory mechanism and have no nitrogen retention. When it is marked in degree, it causes symptoms and needs treatment. The chief factor in its mechanism appears to be low plasma protein levels. High protein intake in the diet is indicated and transfusion may be helpful. Removal of the edema by diuretics should be attempted. The mercurial diuretics, especially mersalyl (salyrgan), or urea in large doses, up to 90 Gm a day, are most effective. With the diuretics there should go a fluid restriction in the diet. A very low sodium chloride intake should be tried. Mechanical removal of the fluid by paracentesis and Southey tubes may be required. Results at best are not very satisfactory. Patients who survive tend to pass over into an edema-free stage of chronic nephritis with increasing anemia, eventually developing nitrogen retention and rising blood pressure, when their management becomes the same as in other forms of chronic nephritis showing these features. As nitrogen retention develops, lowering of food protein is indicated. Periods of low protein intake are beneficial with subsequent return to greater protein content in the food. Protein content of the food needs to be balanced against the level of nonprotein nitrogen in the blood, determined either as urea nitrogen or total nonprotein in the blood. Weekly or biweekly days of marked protein restriction often are helpful. In such dietary restriction of protein there is a necessary limit, because a stage may be reached at which destruction of body tissue contributes to nitrogen retention, and a starved patient is worse off than a fed one, even if nitrogen retention persists. Furthermore, appetite often cannot be maintained with great protein restriction, and freedom of food intake, as dictated by the patient's taste, is preferable to any theoretical restrictions of diet.

If uremia develops and the patient is not very anemic, bleeding is indicated, possibly followed by transfusion. Sweating and purging appear to be of no real help and are too debilitating to use.

Slighter degrees of anemia are to be combated with insistence on an adequate varied diet with proper vitamin content. Protein is important unless its use must be restricted by reason of nitrogen retention. Iron in the modern large dosage is indicated. Transfusions have a definite value, especially if anemia becomes more marked. The severe anemia of nephritis responds satisfactorily to no treatment. It is important to recognize that the anemia of nephritis is the result not of bleeding but of toxemia from the nephritis.

With advance in chronic nephritis, elevated blood pressure develops and eventually circulatory failure with edema results. This is the second form of edema encountered in nephritis, referred to as cardiac or circulatory edema.

The circulatory failure of chronic nephritis is to be recognized and treated as any other form of cardiac circulatory insufficiency. Digitalis is the sheet anchor of therapy. I believe in its use when the heart is enlarged, before evidences of circulatory insufficiency appear, using a daily ration of from 0.1 to 0.2 Gm. of powdered leaves continuously.

There is nothing to do about the hypertension of chronic nephritis beyond recognizing it as an added load on the heart and so restrict other cardiac loads in proportion to the hypertension and particularly after the heart becomes hypertrophied enough to be easily demonstrated as enlarged by simple physical examination. If renal function is poor a fall in blood pressure is one of the worst things that can happen. Luckily it is that the physician has almost no ability to lower the high blood pressure of patients with chronic nephritis.

LIPOID NEPHROSIS AND ITS RELATION TO GLOMERULAR NEPHRITIS

EDWIN G. BANNICK, M.D.

ROCHESTER, MINN.

Between 1920 and 1932, approximately 160 patients more than 15 years of age who presented the "nephrotic syndrome" prominently have been carefully studied at the Mayo Clinic, that is the patients displayed marked edema, profuse albuminuria, elevation of the values for blood lipoid and a decrease in the value for serum proteins. Many patients have been admitted more than once, and the subsequent course of most of the patients has been traced.

In thirty cases, a clinical diagnosis of lipoid nephrosis was justified on the first admission according to the strict criteria for diagnosis of this disorder, but in seven of these cases subsequent examinations have shown the development of definite, chronic glomerular nephritis, four patients having died in uremia.

Nineteen cases corresponded to the so-called "mixed nephrosis" that has been referred to in the literature. As a matter of fact, some of the cases that have been reported as examples of lipoid nephrosis in reality belong in this group. Mixed nephrosis differs from typical lipoid nephrosis only because in the former there is slight evidence suggestive of associated nephritis. In eleven cases it was impossible to make a defi-

nite diagnosis of either lipoid nephrosis or mixed nephrosis because of complicating and slightly atypical factors necessitating hair-splitting distinction.

In the remainder of the cases, approximately 100 glomerular nephritis was more advanced, and the cases have been excluded from the present statistical study. It is of passing interest to note, however, that most of these patients have subsequently died in uremia.

My interest has centered chiefly in the first two clinical groups, that is, the group of lipoid nephrosis and that of lipoid nephrosis with a suggestion of associated nephritis. It seems advisable to analyze them separately.

LIPOID NEPHROSIS

The criteria for the diagnosis of lipoid nephrosis are well understood and they have been closely adhered to in these cases. In order to make such a diagnosis, some difficult decisions had to be made in determining what was normal and what was abnormal. Some of the standards were perhaps too exacting, but if a statistical study such as this is to be reliable, certain arbitrary standards of measurement must be set up so that the reader may have a clear idea of the case under discussion.

In all cases there was marked generalized edema, and in all the history was given that this edema had been present for two months at least. In most cases the edema was of insidious onset. All patients had heavy and persistent albuminuria, all but a few were subjected to complete studies of blood cholesterol, serum protein and basal metabolism, and in all cases the values for blood cholesterol were significantly increased and those for serum proteins were significantly decreased. The basal metabolic rate was decreased in most cases but in some was within normal limits. I have not felt that a basal metabolic rate within normal limits was sufficient in itself, to preclude the diagnosis of lipoid nephrosis especially if correction was made for the false increase in weight due to edema. No patient had increased blood pressure or evidences of previous hypertension such as cardiac enlargement or retinal changes. Systolic blood pressures of more than 140 mm. of mercury and diastolic pressures of more than 90 mm. were arbitrarily regarded as abnormal, the younger patients, and most of the others maintained blood pressures considerably below these levels.

No patients had hematuria, anything more than an occasional erythrocyte in the urine was regarded as abnormal, and all cases were excluded wherein urinalysis disclosed any more erythrocytes than could reasonably be expected to occur in the urine of a normal person if the urine was examined carefully each day.

No patients had significant renal insufficiency as measured by determinations of urea in whole blood and of excretion of phenolsulphonphthalein. All determinations of urea gave values of less than 40 mg. for each 100 cc. of whole blood, and excretion of phenolsulphonphthalein in all cases was at least 50 per cent in two hours and fifteen minutes.

Significant anemia was not present in any case, erythrocytes in any case did not number less than 4,000,000 in each cubic millimeter of blood. Appraisal of these criteria will establish these cases as clinical examples of lipoid nephrosis, and such a diagnosis was agreed on by several physicians who independently examined the patients or studied their records.

In this group of thirty patients there were twenty-one males and nine females, a difference which I am

From the Division of Medicine, the Mayo Clinic.
Because of lack of space, references to some of the literature are omitted here. This omitted material will appear in the reprints.
Read before the Section on Pathology and Physiology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

unable to explain. Their ages on admission ranged from 15 to 72 years. All patients who are less than 15 years of age are treated, at the clinic, in the section on pediatrics, this accounts for the arbitrary lower limit of age. Twenty-two patients were between 15 and 40 years of age, five between 40 and 50 years, and three, more than 50 years. The onset of the edema was insidious in sixteen cases. It followed exposure in four cases, influenza in three, syphilis and treatment for syphilis in two, tonsillitis in two, diphtheria in one, chickenpox in one and an alcoholic debauch in one.

Practically the same etiologic ratio existed in the seven cases of the thirty just mentioned in which glomerular nephritis developed later. In four of these the onset was insidious, in two it followed exposure, and in one it followed tonsillitis.

Most of the thirty patients have been reexamined at the clinic and an attempt has been made to follow the subsequent course of the illness at home. The data obtained as a result of these studies are interesting and I think valuable. They are summarized as follows:

Apparently cured, seven patients, traced, six and a half, five, eleven and a half, one and a half, seven, two and five years, respectively.

Reported themselves "fine" but laboratory data not furnished, nine patients, traced, three and a half, three, five, eight and a half, five, seven and a half, four, three and three years, respectively.

Markedly improved, four patients, traced, two, seven and a half, two and a half and five years, respectively.

Symptomatically improved but with glomerular nephritis, two patients, traced, nine and seven years, respectively.

No improvement, one patient, traced one year.

Dead, seven patients. Two of these seven patients died at the clinic, one of septicemia, and the presence of mild glomerular nephritis was confirmed at necropsy, one in uremia, from chronic glomerular nephritis which was confirmed at necropsy. Five died at home, three in uremia from chronic glomerular nephritis and two of causes not determined.

A study of the foregoing summary of the thirty cases impresses one with the fact that as a group these patients have ultimately done surprisingly well, significantly better than a similar group of patients with chronic glomerular nephritis would have done. Previously a relevant prognostic study has been reported from the clinic.⁶ In children the prognosis is apparently not so good, probably owing in part at least to the difficulties in treatment and to the more frequent occurrence of intercurrent infections.

As has been emphasized often the course of the illness, even of those who ultimately recover, is usually characterized by recurrence of, or exacerbations of, the edema and variation in the degree of albuminuria.

The seven patients who have been considered apparently cured have all been entirely free from any symptoms of disease for a considerable period of time and have all been examined and found to be apparently normal. Repeated urinalyses in each case have given normal results. Of course it is always possible that this "cure" may not be permanent, but these seven patients at least demonstrate that striking recovery is possible.

Without the opportunity for careful examination of the nine other patients who have reported that they were feeling well and were not having any trouble it is impossible to determine what percentage of them might be apparently cured or what percentage might have

residual abnormalities. Summing up these cases, it is evident that twenty patients, exactly two thirds of the entire group, have made marked symptomatic improvement.

The insidious onset of this disease, with such a relatively high proportion of recovery of patients who had had such marked symptoms for months and even years, makes the clinical course different from that in ordinary chronic glomerular nephritis, and provides some basis for the theories of those who claim that this disorder is an entirely separate entity from glomerular nephritis. But this argument is immediately met with one based on the fact that in some of these cases definite glomerular nephritis develops and the patients die in uremia. The statements in the literature that patients with lipoid nephrosis never die in uremia from glomerular nephritis are wrong, if my observations are correct.

Surely, if glomerular nephritis can be proved to have developed in seven of thirty cases of lipoid nephrosis, there must be some intimate relationship between the two diseases. This incidence is too high to be explained on a purely accidental basis.

It is necessary to prove, therefore, in the first place that these seven cases were instances of lipoid nephrosis, and in the second place that glomerular nephritis actually developed. Thus I have tried to do in table 1 and the following notes on the cases.

CASE 1 (table 1).—The onset was insidious. In addition to the data recorded Aug 10, 1927, doubly refractive lipoid bodies were found in the urine. Significant data remained unchanged during fourteen days of observation, except that the patient lost 9 Kg of edema fluid without any medication. It is to be emphasized that the patient had had edema off and on for three and a half years before admission and that at times it had been marked. He was dismissed August 24 with an unqualified diagnosis of lipoid nephrosis.

When he was reexamined May 21, 1928, early signs of nephritis were noted, the blood pressure was slightly elevated, and there was some anemia. In the meantime his edema had disappeared without medication, and it never again recurred. On two subsequent examinations, July 15, 1929, and Aug 18, 1930, there was definite progression of glomerular nephritis, as indicated by hypertension, anemia, an elevated value for blood urea and a markedly decreased excretion of phenolsulphonphthalein. Weakness progressed slowly, and the man died at home Sept 29, 1932, in uremia.

CASE 2 (table 1).—The data recorded in June, 1928, and October, 1928 were sent in by the patient's physician in Chicago. In June, daily urinalysis for many days disclosed persistent albuminuria, and only once or twice an occasional erythrocyte. Repeated readings of blood pressure were around 130 systolic, on one occasion pressures of 150 systolic and 80 diastolic were recorded. The edema subsided but recurred, and the patient was hospitalized in October, 1928 (table 1). A diagnosis of lipoid nephrosis was made at that time. Subsequently edema recurred again and the patient was sent to the clinic Jan 22 1929 (table 1). He was in the hospital twenty-one days. Readings of blood pressure taken daily were all normal except one reading which was recorded as 145 systolic and 80 diastolic. On dismissal, erythrocytes numbered 3,980,000. All other data remained unchanged. A diagnosis of lipoid nephrosis was made.

On reexamination, Jan 24 1930, in addition to the elevated value for blood urea the reduction of excretion of phenolsulphonphthalein, the hematuria and the questionable slight hypertension the patient also had mild retinitis. These observations definitely indicated associated glomerular nephritis. The subsequent course of his illness at home was characteristic of slowly progressive renal insufficiency, and the patient died July 19 1932.

6 Bannick, E. G. and Keith, N. M. The Treatment of Nephritis and Nephrosis With Edema. J. A. M. A. 91: 1944-1951 (Dec. 22) 1928.

CASE 3 (table 1)—Following diphtheria, five and a half years previously, albuminuria developed and slight edema had been present at intervals ever since. There was a marked increase of edema a week before admission on Feb 21, 1924. Frequent examination at the clinic over long periods, on one occasion for forty-seven days (March 9 1925), always revealed typical data for lipid nephrosis until October 1927. During this time of observation the patient had required many injections of merbaphen and much ammonium chloride to keep edema under control. Oct 20 1927, the first indications of nephritis occurred when hematuria and an elevated value for blood urea were noted. The hematuria has persisted in varying degrees, and the renal insufficiency has been slowly progressive since that time but hypertension has not occurred. Between 1924 and 1933 the patient required injection of merbaphen at

the only residual sign pointing toward nephritis was the anemia. She continued to have trouble at home and was reexamined Aug. 23, 1930, at which time she was found to be in the end-stage of chronic glomerular nephritis. This progressed until she was in uremia, September 14, with a value for urea of 468 mg in each 100 cc of whole blood. She died at home a few days later.

CASE 5 (table 1)—The edema was of insidious onset. In addition to data noted Aug. 25 1926 doubly refractive lipoids were found in the urine. Significant data were unchanged for thirty days, except for loss of edema (105 Kg). The patient had taken 87 Gm of ammonium nitrate, 90 Gm of ammonium chloride and 65 cc of merbaphen (nine injections) during this period. She was dismissed September 22, with a diagnosis of lipid nephrosis. Edema recurred when she was at home, and

TABLE 1—Cases of Lipoid Nephrosis With Subsequent Glomerular Nephritis

irregular intervals, and took much mercury in this way but had always responded well to these injections. The patient reported, May 4 1933, that she was having little trouble in controlling edema, probably owing to the slow development of a contracted kidney.

CASE 4 (table 1)—The edema was of insidious onset. On examination, July 28, 1926 the data were those of lipid nephrosis, and there was no significant change in the data for twenty-seven days, in spite of a prolonged infection of the respiratory tract. On the twentieth day an injection of 0.5 cc of merbaphen was given, and on the twenty-third day an injection of 2 cc of the same substance. This was followed by severe stomatitis. August 24 (twenty-eighth day), a series of convulsions suddenly developed. This episode was followed by an increase in the edema and by hypertension, anemia and renal insufficiency. The patient made a gradual recovery from this exacerbation, however, and on dismissal September 14,

treatment with ammonium nitrate and an occasional injection of merbaphen were necessary. She returned for examination Oct 13 1927, and again her condition was typical of lipid nephrosis, except that the excretion of phenolsulphonphthalein was somewhat diminished. Also occasional erythrocytes were noted in the urine possibly a little more frequently than could be considered normal. She was again treated with ammonium nitrate 124 Gm, and with merbaphen 75 cc (six injections), and was dismissed November 5. She never had much trouble with edema after that but Feb 19, 1929, a definite reduction in excretion of phenolsulphonphthalein was noted, and May 13, 1932 although she had been free from edema for months and had thought she was getting along well, she was found to have typical chronic glomerular nephritis with hypertension, hematuria and renal insufficiency.

CASE 6 (table 1)—Edema was of insidious onset. On admission to the clinic, the patient's condition seemed to be typical

of lipid nephrosis and the data recorded May 10, 1926, remained without any significant change for sixty-six days. During this period the patient had taken 415 Gm of ammonium chloride and 165 cc of merbaphen (nine injections), and had lost 20.5 Kg of edema fluid. The diagnosis of lipid nephrosis seemed unquestionable. On the sixty-seventh day, however, the value for blood urea was elevated, and when the patient was dismissed on the sixty-eighth day, the value for blood urea was 65 mg, and his blood pressures were 140 systolic and 100 diastolic, thereby suggesting a nephritic component. On subsequent examination he was found to have rapidly progressive glomerular nephritis. March 4, 1927, he had marked hypertension, anuria, renal insufficiency and hematuria, and he died in convulsions and coma March 7. At postmortem examination, made at the clinic, the kidneys were contracted and typical of the end-stage of glomerular nephritis.

CASE 7 (table 1).—The onset of edema followed two months after "sore throat." The patient had scarlet fever six months, and tonsillitis four months before admission. In spite of this,

Comment on the Seven Tabulated Cases of Lipoid Nephrosis.—In a critical appraisal of these cases it seems to me that in case 1 clinically pure lipid nephrosis unquestionably was present at one time but that the patient died as a result of renal insufficiency from glomerular nephritis.

The same seems true of case 2, unless the one abnormal blood pressure recorded by the physician at home, among many normal readings, and the one systolic reading of 145 made at the clinic preclude the diagnosis of lipid nephrosis. However, if such a hair-splitting distinction is sufficient to change the diagnosis from lipid nephrosis to glomerular nephritis, then these disorders must certainly be most closely related.

Cases 3, 4, 5 and 6 seem to be without question examples of definite lipid nephrosis changing into unmistakable glomerular nephritis. The only question

the data seemed typical of lipid nephrosis on admission of the patient to the clinic April 11, 1929. Significant data were unchanged for twenty-seven days except for the loss of 12 Kg of edema fluid. During this time the patient had taken 160 Gm of ammonium nitrate and 25 cc of merbaphen (two injections). Tonsillectomy was performed May 8. Septicemia developed May 10, on which date the value of blood urea was still normal, and hematuria was not noted. The following day, however, gross hematuria occurred. The patient died May 12, as a result of the septicemia. At postmortem examination the kidneys were large, together weighing 523 Gm. The changes in the glomeruli were uniform and consisted of proliferation and swelling of endothelial cells with partial obstruction of many of the capillary loops and complete obstruction of a few. The association of numerous polymorphonuclear cells with the proliferated endothelium suggested that an acute process was present. Changes in the glomerular membrane were not marked and consisted of occasional areas of slight thickening. Tubular changes were marked, whereas the interstitial changes were not altered.

that can be raised in these cases is concerning the fact that merbaphen was given in all of them. In cases 5 and 6, this does not seem to sustain a reasonable objection, because neither of the patients received much merbaphen and both responded well to it. Furthermore, there is no reason to think that mercury would produce glomerular nephritis, and for this reason cases 3 and 4 are also probably not to be questioned.

In case 7 two objections might be raised: first, that the onset following "sore throat," with a history of only two months' duration, precluded a diagnosis of lipid nephrosis, and second, that the glomerular changes noted at postmortem examination were the result of the terminal infection and were therefore manifestations of incidental acute nephritis. It is seen at a glance that these two objections are paradoxical, so that neither seems very plausible. At any rate, this case presented the clinical data of lipid nephrosis, and

at postmortem examination there was evidence of mild glomerular nephritis in addition to the tubular changes characteristic of lipid nephrosis.

LIPOID NEPHROSIS WITH SLIGHT EVIDENCE OF NEPHRITIS (MIXED NEPHROSIS) NINETEEN CASES

An insufficient number of these cases is reported in the literature, since careful and complete clinical and pathologic studies of such cases may aid in ultimately determining the exact relationship between lipid nephrosis and glomerular nephritis. Wilbur and I intend to publish such a detailed study soon and therefore I will make only a brief report of some such cases at this time.

The age incidence and the etiology coincided well with those of typical lipid nephrosis. There were eleven males and eight females; twelve were between 15 and 40 years of age, three, between 40 and 50 years of age, and four between 60 and 70 years of age. The onset of the disease was insidious in fifteen cases, occurred during pregnancy in three cases and followed exposure in one case. Attention is called to the proportion of occurrence among older persons. These nineteen cases are summarized as follows:

Cured, no known cases

Reported themselves fine, but laboratory data not furnished, three patients, traced, six, four and three years, respectively.

Symptomatically improved, but with nephritis, two patients, traced six and two years, respectively.

No report one patient

Dead, twelve patients. Seven of these twelve patients died at the clinic. One of the seven died in uremia and necropsy confirmed the presence of the end-stage of glomerular nephritis, in one case necropsy confirmed the presence of progressive glomerular nephritis and pericarditis. Five died primarily from complicating disease. One of the five had infected ascites and anasarca, and necropsy confirmed that considerable glomerular nephritis was present. In the other four of the five cases necropsy disclosed large pale kidneys and marked tubular changes and in three of the four there were slight but definite glomerular changes, whereas in one of the four the glomeruli seemed normal. One of these four patients had cellulitis sepsis and pericarditis, one, pneumonia and empyema, one pneumonia, and one, anasarca, convulsions and hyperpyrexia. Five of the twelve patients died at home; two of progressive glomerular nephritis and three of causes that were not determined.

When the data just summarized are compared with those presented in the summary of the thirty cases of lipid nephrosis given earlier in this paper, the difference in prognosis is at once striking. Not only is there a much higher mortality rate among the patients who had lipid nephrosis with slight evidence of nephritis (mixed nephrosis) but also absence of known cure. Another probably significant observation is the much higher incidence in cases of mixed nephrosis of death resulting from complicating infections, half of the deaths occurred in this way. This probably can be explained by the facts that patients who have mixed nephrosis do not as a group respond to treatment as well, more difficulty is experienced in keeping the edema under control, and this, together with such other factors as retention of urea, and anemia, prepares the soil for intercurrent infection.

Postmortem examinations were performed at the clinic in seven cases, and a brief clinical and pathologic

abstract of these cases is included in table 2 and the case histories. The pathologic studies were made by Wilbur and represent a portion of those that will be reported in detail later. Notes on the seven cases follow.

CASE 8 (table 2).—Albuminuria had been noted three years before the patient came to the clinic. Edema had come on insidiously six months before admission. At the time of the first examination, March 28, 1927, in addition to the data recorded, doubly retractive lipoids were found in the urine, and lipemia retinalis was noted. All data pointed to lipid nephrosis except the fact that erythrocytes occurred in the urine slightly more frequently than usual, and soon (April 13) urinalyses gave entirely negative results for blood, at which time the data were those of typical lipid nephrosis. However a little later, the value for blood urea became elevated during a course of treatment with ammonium nitrate, but this also promptly returned to normal. The factors mentioned however precluded a diagnosis of uncomplicated lipid nephrosis at the time when the patient was dismissed, April 21, after nearly a month of treatment. On subsequent examinations Aug. 6, June 28, 1928 and Nov. 13, 1929, the progression of glomerular nephritis was noted and the patient died in uremia. Postmortem examination disclosed the contracted kidneys typical of the end-stage of glomerular nephritis.

CASE 9 (table 2).—Anasarca which became extreme, was of insidious onset. Readings of blood pressure were unreliable because of great edema of the arms. Signs of renal insufficiency slowly progressed, but pericarditis developed and the patient died in coma, Dec. 16, 1925 before renal insufficiency alone would have caused his death. At postmortem examination the kidneys were large, together weighing 408 Gm. The predominant pathologic picture was the marked tubular changes, nevertheless, evidence of glomerular nephritis, not yet in an advanced stage, was unmistakable.

CASE 10 (table 2).—Massive anasarca was of insidious onset. Abdominal paracentesis had been performed five times before the patient's admission to the clinic, and milky fluid had been withdrawn each time. The patient died suddenly, while vomiting twenty-four hours after admission. At postmortem examination ascites (approximately 11,000 cc) with infected fluid and bilateral hydrothorax were discovered. The kidneys were small, together weighing only 209 Gm, and contained surprising changes in view of the marked clinical evidence of nephrosis and the slight clinical evidence of nephritis. The glomeruli presented all stages of change from an almost normal condition to that of markedly thickened basement membranes, endothelial proliferation, formation of hyaline fibers and complete obstruction of the capillary loops. Crescents were absent. Marked changes were noted in the tubules and interstitial tissue.

CASE 11 (table 2).—The patient came to the clinic, Nov. 1, 1926 because of a tremor, at which time slight hypertension and a faint trace of edema of the ankles were noted. Urinalyses disclosed slight albuminuria and slight hematuria, but these were not particularly significant because of marked pyuria owing to vaginal discharge. Exactly a year later she returned again this time with extreme anasarca which had begun insidiously two months before. Hematuria had occurred at home. The data noted Nov. 1, 1927, were atypical for uncomplicated lipid nephrosis because of slight hypertension, anemia and renal insufficiency, but all of these were relatively mild. November 3 there was a marked increase in the edema of the face and head and the patient suddenly began to have a series of convulsions following one of which her blood pressures were recorded as 160 mm. of mercury systolic and 120 diastolic. Coma and hyperpyrexia followed and the patient died November 7. The last temperature recorded was 106.2 F.

At postmortem examination nothing significantly abnormal was noted, except in relation to the kidneys. They were large weighing together 472 Gm. There were some changes in the glomeruli in most instances, the alterations were chiefly slight to moderate proliferation and swelling of endothelial cells.

These changes were patchy and variable in degree and stage of development. The loops in some tufts were obstructed, but practically no tufts were completely occluded. The basement membrane was thickened in some areas but this was not a striking feature in the majority of the glomeruli. The tubular and interstitial changes were markedly out of proportion to the glomerular changes.

CASE 12 (table 2)—The onset followed exposure. The edema began in the face and was of insidious development. Data assembled March 12, 1925, were not typical of lipoid nephrosis because of the presence of renal insufficiency, anemia and erythrocytes in the urine. March 14 cellulitis of the abdominal wall occurred and became extensive. The patient died March 22, of sepsis and terminal pericarditis. The terminal value for blood urea was 161 mg in each 100 cc. At postmortem examination the kidneys together weighed 422 Gm. On microscopic examination, the tufts appeared essentially normal. Albumin and granular material were present in the capsular spaces, and some of the tufts presented evidence of thickening about the hilus concomitant with the age of the patient. The glomerular membrane was essentially normal in every tuft. The prominent changes were in the tubules, and to some extent in the interstitial tissues.

CASE 13 (table 2)—This patient was first seen at the clinic March 5, 1919, at which time she was found to have chronic arthritis and infected tonsils. Albuminuria was noted at that time. She was readmitted April 19, 1926, because of the insidious onset of edema two months before. She had been having much trouble with arthritis also. Marked nephrotic features were noted on admission, but also evidences of renal insufficiency. The congo red test for amyloid disease gave a normal response. She responded poorly to treatment for the edema and finally contracted bilateral bronchopneumonia and died May 26.

At postmortem examination the kidneys together weighed 306 Gm. Marked changes were observed in the tubules and in the interstitial tissue. There was evidence of mild but definite glomerular nephritis.

CASE 14 (table 2)—Edema was of insidious onset. On his first admission Sept. 30, 1926, the patient's condition was typical of lipoid nephrosis, except for slight hypertension and slight anemia. The only significant changes noted on his second admission March 4, 1927, were slight progression of the hypertension and the anemia. April 5, bronchopneumonia developed, then bilateral empyema and parotitis. Progressive renal insufficiency followed, and the patient died May 8. At postmortem examination, the kidneys were found to be very large together weighing 666 Gm.

The glomeruli presented appearances varying from normal to marked changes and complete hyalinization. Endothelial increase and fatty degeneration, thickening and fraying of the basement membrane were present in variable degrees in nearly all tufts. Crescents and hyaline fibers were not observed. A large proportion of the glomeruli were so diseased as to be functionally useless. Tubular and interstitial changes were marked.

Comment on the Seven Tabulated Cases of Mixed Nephrosis—Appraisal of the contents of table 2 and of the notes on the cases brings out some interesting observations.

In all of these cases in which necropsy was performed (except one case 12) there was both clinical and pathologic evidence of associated glomerular nephritis. Case 12 gave clinical evidence of nephritis (marked renal insufficiency and anemia) but there were no significant glomerular changes. Several pathologists made careful studies, using the special method of staining recommended by Bell⁸ and McGregor.⁹

The finding of essentially normal glomeruli in case 12 could be interpreted in two ways: either that this was an example of pure lipoid nephrosis, and that the renal insufficiency and anemia noted clinically were the result of the tubular changes and extrarenal factors; or that some degree of glomerular nephritis, or at least of glomerular insufficiency, existed, even though it could not be definitely demonstrated by microscopic studies. Because of the relatively short history (two and a half months) and the large kidneys, I think the latter explanation is more plausible.

In spite of clinical evidence of associated glomerular nephritis the kidneys were large and pale in five of the seven cases and in four of the seven the glomerular changes were slight as compared to the tubular changes. Cases 11 and 12 were practically typical examples of the pathologic picture attributed to lipoid nephrosis. These observations would indicate that glomerular nephritis may exist without producing the usual pathologic changes that one has been taught to anticipate in chronic glomerular nephritis. This would seem to favor Bell's ideas as to the pathogenesis of lipoid nephrosis.

The relatively slight glomerular changes and the absence of any significant changes in one case would indicate on the other hand, that both clinically and pathologically some of these mixed cases differ from ordinary chronic glomerular nephritis. Whether it is a matter of degree of capillary occlusion and so forth as suggested by Bell, I am not prepared to say from this study and from my limited pathologic experience. But at any rate the fact that the glomerular changes are relatively slight even in some of these cases in which there was definite clinical evidence of nephritis, explains why patients with typical lipoid nephrosis not infrequently recover.

The pathologic evidence of mild glomerular nephritis cannot be attributed to the terminal infection in these cases, because they presented clinical evidence of some glomerular nephritis before a terminal infection developed.

In these cases of mixed nephrosis it is not possible accurately to predict just what pathologic changes necropsy will reveal. Christian¹⁰ aptly stated this when he wrote: "As clinicians, I think we should recognize that we may be unable during life to predict accurately whether the pathologist is going to find more or less nephrosis or less or more nephritis." Clinically the patient whose condition was nearest to typical lipoid nephrosis was the one in case 10, and his kidneys were small and contained rather marked glomerular changes, whereas in case 12, in which there were practically no glomerular changes I had expected to find considerable glomerular change.

SUMMARY

The present study of lipoid nephrosis and the so-called 'nephrotic syndrome' suggests that lipoid nephrosis, in adults at least, is a form of Bright's disease.

The frequent association of lipoid nephrosis with definite glomerular nephritis, the fact that cases of clinically pure lipoid nephrosis may terminate in uremia from the end-stages of glomerular nephritis, and the fact that not a single case typical of lipoid nephrosis in an adult has come to postmortem examina-

tion at the Mayo Clinic suggest that at least most cases of lipid nephrosis represent a stage in, or an unusual type of, glomerular nephritis. If other cases occur they are extremely rare.

The relatively high percentage of patients who have been cured of lipid nephrosis or who have shown marked and prolonged improvement and the relatively slight evidence of glomerular nephritis in most instances at postmortem examination even among patients who have given clinical evidence of glomerular nephritis, justify the grouping of these patients clinically in a separate group from that of ordinary glomerular nephritis. As long as the term lipid nephrosis has been so uniformly accepted there seems to be no good reason for changing it.

ABSTRACT OF DISCUSSION

DR M. H. BARKER, Chicago. The problem of the waterlogged patient with renal disease is very broad and difficult to interpret. It is obvious that in the presentation by Dr Bannick a large number of cases fall well within the classification of the nephrotic syndrome. However as he points out time and study of these cases bring many of them to an end that cannot be differentiated from that of the regular course of renal disease of the glomerular type. Clinical and experimental studies indicate clearly as Dr Bannick has concluded that that group of cases should be set apart for consideration, certainly from the standpoint of dietary and therapeutic management. I am sure that the dietary plan used and the fluid balance control served to bring many of these to a period of apparent recovery and again, to prolong the lives of others. I am sure that a large number that develop edema and convulsions, or renal edema with nitrogen retention, are not infrequent in this acute stage. The control of that phase is making it possible to carry many more on to a period of possible recovery. My experience comedes with the results of this study. Some of the purest types have gone on to renal failure and to contracted kidneys. I have studied a group from the standpoint of the onset. All of those which I had a chance to follow up from the beginning started with an acute nephritis. It may have been very mild, a week or ten days, but with the ensuing albuminuria the nephrotic syndrome followed. Flat roentgenograms show large kidneys. As the edema subsides or is controlled, the size of the kidney comes down. The cases that have come to autopsy presented these peculiar mixed glomerular lesions with other evidence of degenerative changes. One must keep the nephrotic groups in mind, as a different group from the standpoint of therapy. Since, however the majority of the syndromes may be a part of the glomerular renal disease with a phase in which the albuminuria and edema are the chief signs, one must not lose sight of the disease by focusing attention, for the moment, on the individual stage.

DR DAUGHT L. WILBUR, Rochester, Minn. I have had the opportunity of studying the kidneys, and particularly the glomeruli, in the cases reported by Dr Bannick. I can verify the presence of the pathologic changes which he mentioned. There are two points which I would like to emphasize with regard to this problem. In almost all cases presenting the nephrotic syndrome, glomerular lesions, often of a mild degree, were demonstrated, regardless of the presence or absence of clinical evidence of glomerular nephritis, and without respect to the stage of the disease at the time of death. Up to the present time the renal lesion is the only outstanding one that has been observed in these cases post mortem. These facts strongly emphasize the view expressed by Dr Bannick that those cases in which the nephrotic syndrome is present in adults are in reality examples of a stage or a type of glomerular nephritis. However, it cannot be denied that certain cases which clinically present the nephrotic syndrome may, at postmortem examination, show glomeruli that appear normal histologically. The number of such cases noted in the literature is so small, and existing knowledge of the pathogenesis of such renal lesions is so meager and controversial, that caution is needed before stating the relationship or the absence of relationship between

these cases and those of glomerular nephritis. There is not as yet sufficient knowledge to settle this problem satisfactorily. One of the greatest difficulties is the present inability to correlate the anatomic and physiologic changes occurring in renal disease as so aptly expressed by Christman. "I think we should recognize that we may be unable during life to predict accurately whether the pathologist is going to find more or less nephrosis or less or more nephritis."

DR I. G. BANNICK, Rochester, Minn. Dr Barker raised an interesting question concerning the etiology of these cases, namely, whether those in which typical glomerular nephritis subsequently developed presented a different etiology or onset from the others. This thought had also occurred to me, but after careful study I found that this was not true in this series of cases. Practically the same etiologic ratio existed in the seven patients who later developed glomerular nephritis as in the other patients. In four of the seven the onset was apparently insidious, in two it followed exposure, and in only one case did it follow an acute infection (tonsillitis). Dr Barker made another suggestion with which I concur, and that is that for the time being, at least these cases of lipid nephrosis should be retained as a clinical group separate from the cases of ordinary chronic glomerular nephritis, and in this way more light may be thrown on this problem as well as on the larger ones dealing with renal pathology and physiology in general. It should be appreciated, however, that the clinical and pathologic picture may change, and before a physician attempts to say much about the prognosis of a given case of lipid nephrosis he must have the opportunity of repeated observations and careful study. Under these conditions if the same absence of evidence of nephritis persists as time goes on it becomes progressively safer to venture a prognosis.

PROCEDURES FOR THE TREATMENT OF MYELOGENOUS LEUKEMIA

U. V. PORTMANN, MD
CLEVELAND

Myelogenous leukemia is a disease characterized by progressive hyperplasia or proliferation of the myeloid cells of the body. It is clinically manifested by varying degrees of enlargement of the spleen and an abnormal number of immature myeloid cells in the circulating blood. The disease always proceeds, by exacerbations and remissions to a fatal termination.

The profession is still as ignorant of the etiology of myelogenous leukemia as were John Hughes Bennett and Rudolph Virchow when they independently described it in 1845. The fact that the cause of this disease has eluded medical savants has led to extensive investigations of its different aspects in the hope of discovering its mysterious origin or a cure. As a result of these studies, detailed knowledge has accrued concerning the morbid anatomic changes and also about the development and the life cycle of blood cells, all this information is described in the voluminous literature on the subject.

Since 1903, no suggestion for the treatment of myelogenous leukemia has been more successful than irradiation. A survey of the different technical roentgen procedures that have been employed during this period indicates that all of them have been logically based on an understanding of the pathologic changes.

THE TECHNIQS FOR IRRADIATION

The first report of "a case of splenomedullary leukemia successfully treated by the use of the roentgen

ay" came from Dr Nicholas Senn¹ in 1903. The patient was treated by Dr William Allen Pusey, who employed a technic according to the equipment available at that time. At that early period in the history of roentgen therapy the voltage and ampage in the secondary circuit was not measured and filtration of the rays had not yet been discovered, however, the potential on his "medium hard tube" probably was about 80 kilovolts. The tube was placed at from 5 to 8 cm from the skin. According to Senn "the spleen, the lower end of the sternum and the epiphyseal extremities of the long bones" were "exposed to the action of the rays daily for from ten to twenty minutes." The success of this procedure is indicated by the title of the paper and by the conclusion "The microbes of splenomedullary leukemia are very susceptible to the destructive action of the x-ray, and the response to this treatment is very prompt and often violent, followed by a speedy return to normal of the spleen, medullary tissue, and the histologic constituents of the blood."

Three years later "a new and more rational method of treatment of leukemia by x-rays" was suggested by Stengel and Pancoast.² These authors outlined a method of zoning the patient's body with the expectation of treating the entire hemocytopoietic system. They stated that "a four inch vacuum" tube was used and each region treated for fifteen minutes daily. Filters had not yet been introduced. The body was divided into eight regions as follows: (1) the ankles and lower half of the legs, (2) from the middle of the legs to the middle of the thighs, (3) the right half of the abdomen excluding the spleen, (4) the left side correspondingly, (5) the right half of the thorax, shoulder and part of the arm, (6) the left side correspondingly, (7) later treatment to the entire thorax and the shoulders in one field, the spleen being excluded and, finally, (8) the spleen posteriorly to include the pelvis and spine. The different regions were treated successively each day and each was irradiated three times. The results of this procedure were also satisfactory according to their conclusions. "The primary results are as good as those hitherto employed."

Applications to the bone marrow also reduce the size of the spleen and destroy the leukocytes circulating in the blood, but in addition they are more likely to reach and remove the cause of the disease. Since this technic was suggested, it has been rather generally employed with technical modifications, depending on the improvement of apparatus and methods.

A variation of the zoning procedure was made in 1923 by Duke,⁴ who suggested "the treatment of leukemia by irradiation of the chest," as he said, "with the idea in view of applying rays chiefly to the blood (and white cells) by irradiation of the chest in small exposures." The technic described was spark gap, 8 inches, filter, 3 mm of aluminum and sole leather, distance, 10 inches, 5 milliamperes of current for five minutes and the frequency of application governed by the white blood cell count. In Duke's

experience and that of others, this method proved satisfactory.

As early as 1907, Dessauer,⁵ when developing a method to produce homogeneous roentgen rays, suggested treating the entire body for undiagnosed or unlocatable disease by placing the patient in a large room in which two or three tubes at a distance of several meters irradiated the entire body, so that "100 hours of exposure gave 1 H unit." The method of treating the entire body was employed by several others from time to time to treat different diseases. In 1927 Teschendorf⁶ discussed "total irradiation" of the body in connection with leukemic diseases of the blood, and other radiologists have also reported on this method. Recently Hublein⁷ suggested a modification of total irradiation. His method consists of subjecting the patient continuously, day and night, to irradiation from a tube at a great distance (from 18 to 24 feet) operating at 185 kilovolts, 3 milliamperes with filtration of 2 mm of copper with the intensity of from 0.68 to 1.26 roentgen units per hour until from 5 to 30 per cent of an erythema skin dose was given (750 roentgens equals one skin dose). Although Hublein did not live to conclude his experiment, his preliminary report indicated that the results were satisfactory in myelogenous leukemia, and in the hands of other workers his technic is equally satisfactory.

The longest wavelengths of roentgen rays (grenz rays, Bucky⁸) and the shortest gamma rays of radium and all roentgen wavelengths intermediate between the two have an effect on certain white blood cells, causing their elimination from the circulating blood and also destruction of myeloid structures in tissues. It is impossible to state that any one standard technic, based on technical factors of dosage, is preferable to another, because satisfactory results, from the standpoint of changes of the abnormal number or ratio of white blood cells, are obtained by many methods of application of irradiation.

THE EFFECTS OF IRRADIATION

Scientific roentgen therapy was founded on experimental evidence indicating that certain structures are more susceptible to the destructive influences of the rays than others, which clinical experience has corroborated. Albers-Schonberg⁹ in 1902 produced aspermia in rats, Heineke¹⁰ in 1903 found that lymphoid structures are more susceptible to destruction than others, Bergonie and Tribondeau¹¹ in 1904 studied the influence of the rays on the testicles of white rats and formulated their law that "immature cells and cells in an active state of division are more sensitive to the x-rays than are cells which have already acquired their fixed adult morphologic and physiologic characters." Halberstadter¹² in 1905 demonstrated the selective action of the rays on the ovary. Many others have confirmed these observations and enlarged on them, so that there is now a fairly comprehensive idea of the varying degree of radiosensitivity of normal and neo-

plastic cells and tissues, which depends on the degree of differentiation. The most sensitive cells are those primitive cells in the hemocytopoietic tissues which are the precursors of lymphocytes, leukocytes and erythrocytes.

Minot, Buckman and Isaacs¹³ from their studies in myelogenous leukemia concluded that irradiation stimulates the immature phases of the white cells to pass through their life cycles to death and elimination by way of the gastro-intestinal and genito-urinary mucosa with extraordinary rapidity. This conception is well founded on their studies of the ratio of different types of cells both in the blood and in the saliva, preceding during and after irradiation. The theory is not entirely inconsistent with the evidences of direct destruction of other types of cells, which pass through the well known degenerative changes to fibrosis, nor is it contrary to the Bergonie-Lubrondeau law because the immature phases of granulocytes are affected and these do not necessarily undergo the same degenerative changes as tissue cells. But it really does not matter in the application of irradiation for myelogenous leukemia which theory is held because the important factor in treatment is not to rid the circulating blood of its immature cells but to eliminate the radiosensitive myeloid infiltration from the hemocytopoietic tissues so that these may function more or less normally.

Now the question arises as to what organs or tissues of the body should be irradiated and when treatment should be administered. Usually particular attention has been devoted to the spleen, the long bones and the circulating blood; hence, I shall discuss the relative importance of each in the leukemic process.

THE SPLEEN

The spleen has an important hemocytopoietic function only during fetal life and early infancy, but in adults it is of minor significance. It may be removed from a normal person or leukemic patient without materially influencing the production or destruction of white blood cells, its function being assumed by other tissues. In myelogenous leukemia, the spleen may enlarge by invasion of hyperplastic myeloid cells, but this is the result of the disease process and not the cause; nor is the spleen an important site of origin of the white blood cells. During the progress of myelogenous leukemia the spleen undergoes fibrosis, as do other organs, and this is a natural consequence of the disease. It is sometimes contended that the spleen should not be irradiated because fibrosis will result; but this change is no more marked in irradiated spleens removed at autopsy than it is in those which have not been treated. No doubt after a spleen has become fibrosed by the disease irradiation does not cause as much change in the blood manifestations because it contains comparatively fewer blood or myeloid cells to be affected. The spleen should be considered as one of the several structures that are involved in the leukemic process. There is no more indication or contraindication for irradiating it than other tissues and may be done when the enlargement is troublesome to the patient. But it will do little good to treat it when it has become fibrosed, no matter what its size.

THE CIRCULATING BLOOD

The abnormal number and ratio of the immature granulocytes that occur in the circulating blood are a

sign of and the result but not the cause of myelogenous leukemia. The blood is not a tissue and does not become infiltrated by myeloid cells in the manner that other structures are affected and can carry on its functions to a large degree in spite of the abnormality of its cellular constituents, unless the erythrocytogenic tissues are invaded to such a degree that red cell production is reduced. Neither the white nor the red cells are created in the blood, which simply conveys them. Therefore irradiation of the blood per se has no influence whatever on the production of abnormal cells but only removes some of them temporarily, and the hemocytopoietic tissues soon extrude a new crop into the circulation. The elimination of white cells from the blood may or may not always be important, because the presence of abnormal forms or numbers of cells is only an indication of the disease and in itself is not of serious import.

THE LONG BONES

It must also be recalled that it is only during fetal life and early infancy that red hemocytopoietic marrow occupies the shafts of the long bones. It is gradually replaced during adolescence by yellow, inert fatty marrow and only a relatively small amount of red marrow remains at the proximal ends. Neither are the long bones necessarily or always infiltrated by the myeloid leukemic tissue, though at some time during the process the yellow marrow may become more or less displaced. Not infrequently the long bones are quite free from disease when other structures for example the spleen or liver, may be extensively involved. The long bones are relatively of less significance from the standpoint of hemocytogenesis than the vertebrae, the ribs or the sternum, which contain comparatively more red marrow. For this reason it is not a logical procedure always to irradiate the long bones unless there is an indication that they are involved because it will not prevent the occurrence of the leukemic process in any tissue of the body or even free much of the red cell forming marrow.

WHERE AND WHEN TO IRRADIATE

The fact must be recognized that the myeloid leukemic infiltration involves the whole hemocytopoietic system and that during some stages of the disease certain organs or tissues may be extensively involved while others are relatively free, also that for unexplainable reasons, the rapidity of progression and the order in which organs or tissues are affected may vary in different individuals, therefore, acute leukemia and different courses of chronicity are observed. It would seem to be logical to try to determine in each individual case which tissues are particularly in need of irradiation in order to rid them of the disease and to adapt the therapeutic procedure to the individual needs of the patient as indications arise although no case of myelogenous leukemia can ever be cured.

There are some clinical and laboratory manifestations that are danger signals indicating which tissues are infiltrated and should be irradiated. Enlargement of the leukemic spleen is not a serious sign as far as vital functions are concerned, and though the disease does not originate or necessarily extend from this organ it should be irradiated if it is troublesome, even though the progress of the generalized myeloid infiltration cannot be prevented by such treatment. The liver frequently becomes leukemic earlier than is usually suspected, and this organ often is entirely neglected by

¹³ Minot, G. R., Buckman, T. E. and Isaacs, Raphael. Chronic Myelogenous Leukemia. Age, Incidence, Duration and Benefit Derived from Irradiation. J. A. M. A. 82: 1489 (May 10) 1924.

radiologists. When the liver is affected by the disease its cells gradually become atrophic by the pressure of the masses of myeloid cells and as a consequence the liver function is diminished. Therefore enlargement of this organ or evidence that its function is reduced should not be disregarded. Liver function may be studied by the galactose tolerance test and a rising icterus index suggests a serious condition and the necessity for irradiating the liver in order to rid it to some extent of the disease. Occasionally reduced kidney function may handicap a patient and may be determined by a test of the urea clearance or the phenolsulphonphthalein test.

The most important indication for irradiation is the evidence that the erythropoietic tissues are burdened and thus is entirely independent of the presence of abnormality of the white cells in the blood. The principal sign of invasion of the red marrow is anemia with a reduction of the red cell count and of hemoglobin. Associated with leukemia there often is a hemorrhagic diathesis which is probably due to a change in permeability of the capillary walls. This may cause bleeding from the gastro-intestinal or genitourinary mucosa and in the skin, as shown by purpura, or in the joints, causing swelling, pain and limitation of motion. Hemorrhage into the retina causes visual disturbances though these may be so insignificant as to be detectable only with the ophthalmoscope, impairment of hearing, vertigo and sudden deafness are not infrequently caused by bleeding into the labyrinth, and even sudden intracranial hemorrhage may occur. When severe anemia exists or there are evidences of hemorrhage, transfusions should be given to tide the patient over temporarily, but the red bone marrow should also be irradiated. The benefit that ensues from this course of treatment depends on the degree of aplasia or atrophy of the erythropoietic tissue that has been caused by the invasion of the red marrow. Aplasia of the red cell forming tissue is indicated by the absence of reticulocytes in the blood, which also may be studied by obtaining marrow from the sternum with a small punch. If red cells are absent in the marrow, the anemia is aplastic and then little if any benefit can be derived from treatment, because too much of the erythropoietic tissue has already been destroyed.

On the basis of the facts that have been mentioned, treatment should always be administered to the vertebrae, the ribs and the sternum so that these important red marrow bones may function in producing erythrocytes. Of course, the shafts of the long bones may sometimes be affected, as indicated by aching or pain, and in such instances they should also be treated.

CONCLUSION

1 The technical factors governing the dosage of roentgen irradiation for myelogenous leukemia are relatively unimportant so long as the intensity of the rays is therapeutically effective in the region to which they are applied.

2 Myelogenous leukemia is ultimately a generalized disease, progressively affecting certain regions of the body, and the order of the regions affected and the rate of progression vary in different individuals.

3 An abnormal white blood cell count is the result and not the cause of the disease and is significant only when physiologic processes of certain organs are not normal.

4 In administering radiation, it is illogical to irradiate always and as a routine the whole or a single part

of the body. Instead, an effort should be made to cover which vital functions are particularly affected in each patient so that treatment can be administered to the areas involved.

9204 Euclid Avenue

ABSTRACT OF DISCUSSION

DR A U DELSARDINS, Rochester, Minn. I was glad that Dr Portmann mentioned especially the undesirable feature of standardized treatment in cases of leukemia, because every case should be a law unto itself. One case may be relatively acute and another case may be quite chronic. I have a patient who requires treatment only every six months. Another patient may have to be treated much more frequently in order to keep the leukocytes down to a reasonable level. I agree with Dr Portmann that treatment should be directed to the organs mainly affected. In some cases the spleen is so large that it is necessary to bring it down to relieve symptoms. Although direct irradiation of the spleen is advisable in order to reduce the number of leukocytes more quickly. Occasionally, after the spleen and long bones have been irradiated, the number of leukocytes diminishes very slowly. I recall two such cases during the last six months. One presented a leukocyte count of 135,000. In spite of thorough irradiation of the spleen and the main long bones, the number of leukocytes did not fall below 100,000 during the ensuing month. When the patient returned, a second course of treatment was given, the number of leukocytes then fell to about 76,000. Only after a third course of treatment did the number of leukocytes fall below 50,000. Out of a large number of cases I have seen only two that reacted so slowly. In many cases the leukocyte count may drop from 350,000 to 50,000 within a month. One should aim at reducing the leukocytes to 25,000 or below and to keep them as nearly as possible at this numerical level. In some cases this is difficult or impossible, but in the majority it can be done quite readily. At present there is a confusion among pathologists with reference to irradiating only bones that contain red marrow. Some object to irradiating the long bones at all. I have had cases in which the long bones were irradiated but the number of leukocytes could not be reduced sufficiently until the long bones were exposed to the rays. In this in spite of the fact that as brought out by Dr Portmann the main elements of disease are at least anatomically and histologically, situated in the bones containing red marrow.

DR U V PORTMANN, Cleveland. I see many cases in which there is very early leukemic involvement of the long bones but there is no more reduction of the white cells from irradiating the bones than if the treatment were given to another part of the body, as the neck or the blood vessels. It is easy to ascertain this in any patient by giving exactly the same dose of radiation per square centimeter to several fields. There will be no more reduction of the white cells when the bones are treated than when the same dose is given over the liver or the spleen. In fact, in the latter fields there is even greater reduction of the cells because of the greater circulation of blood and greater leukemic infiltration in these organs.

The Odor of the Breath—The breath has many important smells. I find that noses vary enormously in their ability to detect this. I have formed the habit of asking my ward clerks to smell the breaths of diabetic patients in the wards, and when the pleasant, faintly fruity odor is evident to me I commonly find that it is undetected by something like one third to one half of the firm. Apart from making the diagnosis of diabetes in the presence of glycosuria, it may also quickly settle the cause of a coma and so help to save a life. The uremic breath is another important one, but difficult to describe. It is only moderately unpleasant. It has somewhat fishy qualities, it is not exactly a urinous smell and yet it is reminiscent of urine just as halitosis is somehow reminiscent of bowel contents. I have not yet determined how constantly and at what level of the rising tide of nitrogen retention it becomes appreciable in the breath but it has helped me to the diagnosis and prognosis of advanced renal disease.—Ryle J. A. T. Training and Use of the Senses in Clinical Work, *Gen. & Hosp. Gaz.* 47 421 (Oct. 28) 1933.

TRAUMATIC INJURIES OF THE UPPER URINARY TRACT FOLLOWING INSTRUMENTATION

R. B. HENLINE, M.D.
NEW YORK

Attention is being continuously directed to new claims regarding the advantages of intravenous urography. These apply not only to its diagnostic value but also to its usefulness in permitting a more accurate outlining of treatment. Neither excretory urography nor pyelography should be depended on entirely in all cases, but a combination of the two methods will afford a clearer conception of the condition present. This applies with particular truth to cases of ureteral injury.

Traumatic injuries of the ureter resulting from external violence are exceedingly rare and are usually accompanied by serious injury to some other organ or to the bony structure. Unilateral operative wounds of the ureter are relatively common, particularly following pelvic surgery. According to the literature instrumental rupture of the ureter following intra-ureteral manipulation is apparently rare but it is my impression that these injuries occur more frequently than the reported cases would indicate. The fact that my attention has recently been called to several such injuries has stimulated the following report of cases and experimental study.

The extreme resistance of the normal ureter to trauma makes it impervious to rupture with a ureteral catheter or bougie. This is not true if a wire stylet or a whalebone filiform is used. However a ureter diseased by a fibrous stricture, ulceration, acute infection or incarcerated stone lends itself more readily to perforation, and, since it is with diseased ureters that one usually deals, occasional rupture of the ureter is not inexplicable.

Ruptured pathologic ureters may be divided into two distinct groups: first, those in which the ureteral catheter or other instrument actually perforates the ureter—a rare type of rupture, and, second, those presenting a cracking or splitting of the ureter in a longitudinal plane, rendering it sieve-like to injected fluids. This type is not rare, and may result from the passage of even a small catheter or bougie into a ureter so affected by disease as to be rendered friable and deprived of its normal elasticity. This may also occur in the ureter, as in the urethra, from a too rapid dilation of a strictured area. Attempts to dislodge a stone embedded in the canal may force the stone through the ureter, or manipulation of a stone in an infected necrotic ureter may cause its sharp edges to open the ureter sufficiently to allow the escape of injected fluid. Undue pressure from injected pyelographic mediums may permit extravasation from an ulcerated ureter. Too frequent manipulations of diseased ureters also predispose to rupture, therefore, irritation and edema incident to ureteral instrumentation should be allowed to subside before a continuance of treatment is indicated.

These minor extravasations from the ureter usually pass unrecognized, unless an injected ureterogram is done directly after the ureteral manipulation. If the

leakage is minimal in amount, with prompt tissue reaction surrounding the ureter, and if the drainage from the point of rupture to the bladder is satisfactory, the incident will pass unnoticed. The intrarenal or intra-ureteral pressure is not increased, and the urine excreted from the kidney will all pass into the bladder. But if there is an obstruction distal to the rupture, so that the urine excreted from the kidney extravasates from the ureter into the retroperitoneal space, the condition demands surgical drainage.

LITERATURE

The literature contains but few reports of a ruptured ureter following cystoscopic treatment. Hunner¹ has covered the subject most completely in reporting twenty-one cases of ruptured ureters in more than 20,000 catheterizations, only ten of which required surgical drainage. This he states, is not alarming when one considers that diseased, fragile organs are being worked on. He outlines essentials for the prevention of these accidents and emphasizes the necessity for gentleness at all times. A ureter should not be subjected to catheterization oftener than once in ten days, that is, until the trauma and swelling of the last treatment have subsided.

Sargent² reported a case which he diagnosed as a ruptured ureter, unfortunately stating that the accident occurred following passage of a number 5 F catheter into a normal ureter. According to the history of long standing infection with treatment and the pyelogram shown it would seem that the ureter in this case was considerably damaged. A perforation of the ureter following an attempt to remove a ureteral stone, was reported by Noble.³ The ureteral catheter used as a guide was removed from the peritoneal cavity and the ureter sutured. Geisinger⁴ recently reported two cases of ruptured ureter, each of which contained calculi. In both instances the extravasated urine drained back into the ureter which apparently healed promptly.

Young⁵ reported a case of ruptured ureter following the introduction of a ureteral catheter containing a copper stylet. There was considerable local pain and a temperature as high as 103 F, but at the end of seven days the patient was discharged no worse for her experience. Dourmaskin⁶ states that he has never been able to demonstrate a rupture of the ureter but believes that this accident frequently occurs without producing extravasation of urine. Wesson⁷ collected four additional cases of ruptured ureter, in all of which either calculi or marked periureteral infection was present. He has proved conclusively, by experimental evidence, that it is impossible to rupture a normal ureter with the ordinary ureteral catheters and bougies. Catheters and bougies as large as number 11 F were forcibly inserted into normal ureters that had been kinked, knotted and twisted. It was impossible to rupture the ureter in a single case. Clamps were applied to the mouth of the ureter and sufficient pressure exerted with an 11 F

Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 14 1933.

Because of lack of space this article is abbreviated here by the omission of several illustrations and some of the reading matter. The complete article appears in the author's reprints.

bougie to tear the ureter from the clamps, but the bougie did not rupture the ureter. Suction pressure of sodium iodide solution likewise resulted in no ureteral ruptures.

PATHOLOGIC CONSIDERATIONS

The dangers of long continued drainage by large, indwelling ureteral catheters have been carefully studied, clinically and experimentally, by Shaw.⁹ The damage to a ureter thus treated, with the inevitable periureteritis, would probably result in the partial loss of the ureter's motor function and elasticity. Cumming and Jarre¹⁰ and Moore¹¹ have studied the motor activity of normal ureters as well as of those which have been the seat of various inflammatory lesions over a long period of time and have found the elasticity of the latter decreased. Ureters thus affected would therefore be amenable to less manipulation and more susceptible to rupture during ureteral procedures.

When a small crack occurs in a pathologic ureter the amount of extravasated fluid is small, the tissue reaction is prompt, and the ureter heals quickly. Drainage from the kidney will follow the line of least resistance and if the ureter is sufficiently open to permit the kidney to empty without back pressure, the ureteral injury will heal kindly. But if there is enough edema in the ureter to prevent easy egress of urine to the bladder, a secondary kidney retention may develop, causing renal colic. Under these circumstances, a small rent in the ureter will permit escape of the urine under pressure into the periureteral tissues. If the edema in the ureter subsides promptly the escaped urine may even drain back into the ureter and thence into the bladder, followed by healing of the ureteral opening.

Occasionally the ureteral instrument may either pierce the ureter or tear it so that extravasation is prompt and profuse. Usually there is also some obstruction to the ureter below the ruptured area. Marked periureteral inflammation from the irritating extravasated urine is evident. This condition requires prompt surgical drainage to conserve life.

REPORT OF CASES

Having had an experience with a case of ruptured ureter almost a year ago and believing the condition to be rare, I have made a search for additional similar cases among the records and pyelograms from several hospitals in and around New York. Nine cases in all have been collected which I believe to be ruptured or punctured pathologic ureters following various cystoscopic procedures.

CASE 1—S U, a man aged 58, complained of frequent urination both day and night for a year past, for which cystoscopy had been performed. Immediately after the cystoscopy he complained of severe pain in the left part of the abdomen radiating to the scrotum and penis, with nausea followed by vomiting and chills. The vomiting subsided in twenty-four hours and the pain gradually decreased, but the chills occurred intermittently until admission to the hospital four days later, Oct 6, 1932. Examination revealed a distended abdomen with some rigidity over the left side most marked halfway between the umbilicus and the anterior superior spine. The abdominal pain and tenderness continued to improve but the temperature was irregular. The urine, which had contained considerable pus was becoming more nearly normal. October 20 neo-iopax

was given intravenously, with the result shown in figures 1 and 2. Following this, pain and tenderness recurred and the temperature rose to 103 F. October 27, an incision was made in the left loin a cavity being opened which contained pus and urine. The patient's condition immediately improved, and on November 12 a number 8 F ureteral catheter was gently inserted to the left kidney pelvis, releasing a continuous flow of urine containing much pus. This catheter was allowed to remain in place five days. Following removal of the catheter the wound healed promptly and the patient was discharged improved.¹²

Apparently, this patient's left ureter was ruptured at cystoscopy, followed by urinary extravasation into the retroperitoneal space. This rupture, together with partial obstruction of the ureter at or near this point, was sufficient to permit excreted urine from the kidney to extravasate into the soft tissues. This was clearly demonstrable by means of the intravenous urogram. The extravasated neo-iopax being mixed with urine made the condition purely surgical. It is interesting to note how promptly the ureter healed after it had been splinted with a ureteral catheter.

Fig 1 (case 1)—Intravenous urogram taken fifteen minutes after injection showing slight extravasation of the contrast medium

CASE 2—W B, a man, aged 38, on Aug 24, 1932, complained of frequent urination and a dull pain in the lower left side of the back. Cystoscopy was done because of these symptoms and of pyuria. There was a small stone in the lower third of the left ureter. Jan 10, 1933, a number 9 F bougie was passed to the left kidney pelvis with slight difficulty. The procedure was accompanied by a definite scratchy sensation. The patient complained of considerable pain the following three days. At this time a second cystoscopy was performed in an attempt at removal of this small calculus. The left ureter was again dilated with a number 9 F bougie with slight difficulty. This was withdrawn and a number 6 catheter passed almost to the left kidney pelvis. Injection of 3 cc of 10 per cent skiodan caused considerable pain. A roentgenogram was taken (fig 3). The patient passed some blood in the urine for twenty-four hours. The abdomen was distended, and the pain and tenderness, limited to the course of the left ureter, remained constant with only slight relief from narcotics. Intravenous neo-iopax was administered, January 15 (fig 4), following which the ureter was exposed surgically. Just above the brim

¹² This case is reported with the permission of Drs Jacob Nemoulin and O S Iowles.

of the pelvis about half a cup of urine was released. The tissues surrounding this area were waterlogged and friable. A small opening in the ureter was found the edges of which appeared slightly blue tinged. A gallbladder probe was inserted through this opening to the bladder and the ureter carefully examined for the presence of a calculus, but none was found. One plan

Fig. 3 (case 2)—Extravasated shiodan after injection of 3 cc. at a point at which the ureter was ruptured Jan. 13, 1933.

catgut suture approximated the serosa around the ureteral injury. Two drains were placed down toward the ureter. Urine drained from the side for eighteen days at which time a 7 F. ureteral catheter was passed to the left kidney and allowed to remain in position for three days. When this was removed, the wound healed promptly. Figure 5 shows a normal kidney and ureter three months after operation.

It seems probable that this ureteral stone was dislodged and carried upward toward the kidney in front of the bougie, where its sharp edge perforated the ureter. Then, too, the ureter was twice dilated with a number 9 F. bougie, with only a three-day interval between the procedures. The trauma and swelling from the first dilation had not subsided, and the ureter was considerably more friable and apt to rupture with the second dilation. At least ten days should have been allowed to elapse before the second dilation.

CASE 3—E. R., a man, aged 32, on June 23, 1931, complained of pain in the right upper portion of the abdomen, of seven months' duration, gradually increasing in intensity. The urine showed a moderate number of clumped pus cells with a culture of *Bacillus proteus*. Pyelography, June 30, showed a marked stricture at the junction of the upper and middle third of the right ureter. The ureter was dilated to number 9 F., following which the patient's symptoms subsided. Aug. 2, 1932, the ureter was again dilated with a number 8 F. bougie and on August 9 with a number 9 F. bougie. Following this last dilation the patient complained of considerable pain in the right kidney region with abdominal distention and some rigidity. The temperature rose to 102.6 F. and the pain was only partially relieved by opiates. August 12, intravenous neo-iopax was given demonstrating the ruptured ureter (figs. 6, 7, 8 and 9). The ureter was exposed, releasing a small amount of urine. It was carefully searched but no opening was found. The sinus drained for twenty-two days, when a number 7 F. ureteral catheter was gently inserted to the right kidney pelvis and allowed to remain in position for three days. Withdrawal of the catheter disclosed that the wound had healed and remained healed.

The ureteral wall was undoubtedly the seat of marked enteritis, with some scar tissue formation from which the normal elasticity had been lost. Pressure from the ureteral bougie undoubtedly caused the wall to become sieve-like, permitting seepage of fluids through it, although the catheter itself probably did not penetrate the ureter. The fact that intravenous neo-iopax showed progressive extravasation of both neo-iopax and urine from this point demanded surgical drainage. Inserting a ureteral catheter again permitted prompt healing of this ureter.

CASE 4—M. A., a woman, aged 22, entering the hospital, Oct. 6, 1930, complained of constantly increasing pain in the right loin of three weeks' duration, accompanied by vomiting. There was some abdominal distention and tenderness over the right upper quadrant. The urine contained many white blood cells. October 14, ureteral catheters were easily passed to each kidney, releasing considerable pus from the right side. Ten cubic centimeters of 12.5 per cent sodium iodide was injected into the right kidney pelvis and a pyelogram made is shown in figure 10. Operation revealed a ruptured ureter from which about 2 ounces (60 cc.) of thin purulent material was released. The kidney was removed because it contained many small abscesses. The patient died from shock and infection.

This ureter was probably the seat of acute infection and extremely friable. It is possible that injection of sodium iodide under these circumstances caused leakage from the ureter. The infected kidney should probably have been removed at a second operation after the infected extravasation had drained.

CASE 5—M. B., a man, aged 43, complained of pain in the right loin of one year's duration, with two attacks of renal colic. Cystoscopy was done, Sept. 6, 1932. A number 6 F. catheter, passed to the right kidney pelvis with difficulty, released a large amount of pus which contained *Staphylococcus albus*. Ten cubic centimeters of 20 per cent sodium iodide was

Fig. 4 (case 2)—Intravenous neo-iopax Jan. 15, 1933. Twenty minutes after injection there was some extravasation in the same area as in figure 3.

injected into the right kidney pelvis. A roentgenogram showed a ruptured ureter near the kidney, with extravasation (fig. 11). The kidney contained several calculi. Operation, Sept. 7, revealed a small amount of fluid around the kidney pelvis; the kidney was removed at this time with considerable difficulty. Convalescence was uneventful.

Probably overdilatation of an acutely inflamed, friable upper ureter resulted in extravasation. The patient presumably survived the nephrectomy for pyonephrosis because it was done within twenty-four hours after a pyelogram was made.

Fig 5 (case 2)—Pyelogram April 18 three months later than figure 4 showing normal kidney and ureter

CASE 6—A woman, aged 55, had complained of pain in her left side for the past three years and had had a draining sinus in the left lumbar region for the past eighteen months. A left perinephric abscess had opened spontaneously one and a half years previously and had been draining ever since. The left kidney was large but not tender. There were mild symptoms of urinary infection, but the urine contained few pus cells. Cystoscopy, March 2, 1933, showed an inflamed bladder. The right ureter was easily catheterized, but a number 6 F catheter would pass only 2 cm up the left ureter. This was withdrawn and a number 6 F bougie passed almost to the left kidney. This was withdrawn and a number 5 X-ray catheter passed the same distance. No urine was obtained and 3 cc of skiodan was injected, causing considerable pain. A roentgenogram (fig 12 A) showed extravasation from the left ureter. The pain subsided in a few hours. March 3, intravenous neo-iopax (fig 12 B) showed a functionless left kidney with no extravasation of fluid from the ruptured ureter. The patient developed no ill effects from the cystoscopy.

Extravasated solution from the ruptured ureter was apparent only following retrograde injection through the ureteral catheter and not shown with the iopax; hence, surgery is not indicated for the ruptured ureter. The skiodan extravasated from the retrograde pyelography will absorb without ill effect.

CASE 9—H W, a man, aged 35 complained of pain in the left kidney region radiating to the inguinal canal, accompanied by nausea, vomiting and hematuria. Cystoscopy was done Aug 20, 1930, at which time bilateral ureteral strictures and nephroptosis were diagnosed. September 13, he returned because of elevation of temperature and pain and was treated by an indwelling ureteral catheter for four days. This procedure was repeated, Oct 15. Feb 12, 1931, he reentered the hospital because of severe pain in the right kidney region and a slight elevation of temperature. A number 8 F retention catheter was passed to the right kidney, releasing a light brown foul-smelling urine. Within three days his symptoms had disappeared. February 26 an unsuccessful attempt was made to catheterize the right ureter. Five days later a catheter was

inserted up the right ureter with difficulty and 15 cc of 20 per cent sodium iodide injected, causing very slight pain (fig 15 A). No apparent reaction followed this cystoscopy, and the patient returned to the outpatient department until March 23, when he entered the hospital for the removal of a left renal calculus. March 22, catheters were passed easily to each kidney pelvis and a pyelogram revealed no evidence of ureteral injury (fig 15 B).

This patient had probably suffered from undiagnosed uric acid calculi. Continued kidney infection, with the repeated use of indwelling ureteral catheters, had undoubtedly so weakened the ureter that it was easily ruptured with a number 6 F catheter. There was apparently sufficient splitting of the ureter to permit the injected fluid to extravasate but not enough to allow extravasation from the excreted kidney urine. This no doubt accounted in part for the lack of general and local reaction.

EXPERIMENTAL DATA

Four female dogs were subjected to cystoscopy under amytal anesthesia. A McCarthy panendoscope, a Brown-Buerger cystoscope, and a McCarthy cystourethroscope were used, the latter instrument being found preferable for this work. In each dog the right ureter was forcibly dilated with a number 9 F bougie. In dog 1 a right pyelo-ureterogram was then taken, showing no damage to the ureter. The left ureter was intentionally ruptured with a sharp silver wire inserted part way up the ureter. This was withdrawn and a number 6 F catheter inserted, followed by the injection of varying amounts of 20 per cent sodium iodide solution. Dog 1 and dog 4 were injected on the following day with neo-iopax. Dog 1 showed extravasation from the left ruptured ureter and a normal right ureter and

Fig 7—Extravasation of neo-iopax twenty minutes after injection same case as in figure 6

kidney. The left ureter of dog 4 had been ruptured with a small wire stylet, and neo-iopax revealed no extravasation.

These experiments are an aid in confirming Wesson's results, namely, that a normal ureter cannot be ruptured

by a catheter or bougie even though it is distended beyond its normal caliber. The left ureter of dog 1, which was intentionally ruptured with a sharp silver wire (about number 6 F) showed extravasation by means of retrograde pyelography. Excretory urography showed the same extravasation in the case in which the ureter was sufficiently torn. In dog 4, in which the

Fig. 9—Extravasation of neopax fifty minutes after injection same case as in figure 6

ureter had been perforated with a small stylet, the opening was so small that excretory urography failed to reveal extravasation.

SYMPTOMS

Cases of rupture of the ureter following cystoscopy may present considerable variation in both the general and the local symptoms. The intensity of the symptoms is neither an accurate guide to the pathologic condition present nor always to be depended on in making a prognosis.

Local Signs—1 Pain is usually the first sign and is sufficient to cause the patient acute suffering with the injection of even 2 or 3 cc. of a pyelographic medium. This pain may be of a knifelike, scalding, stinging, burning or colicky nature, and usually subsides shortly into a dull ache, it may even disappear entirely in a few days, depending partly on the locality of the puncture and the extent of the extravasation. The pain is usually more severe and lasting if the opening is above the pelvic brim and if the excreted urine continues to extravasate.

2 Prolonged anuria following difficulty in passing a ureteral catheter should lead one to think of the possibility of ureteral rupture.

3 Tenderness and rigidity over the affected side are usually marked and continuous, and large doses of narcotics are necessary to relieve this spasm.

4 Diminished urinary output may be present, but this depends on the extent of the blockage from the affected kidney.

5 Bleeding may also occur, but this is not a constant symptom nor is it diagnostic.

6 Abdominal distention is an early and constant sign, probably because of retroperitoneal irritation from the extravasated urine.

7 Lumefaction is usually a late finding and difficult to determine because of the muscle spasm and rigidity.

General Signs—1 Fever and chills are intermittent and may be absent until late, when infection or toxic absorption from the extravasated urine is manifested.

2 Nausea and vomiting are common early and usually disappear in from twenty-four to thirty-six hours.

3 The leg on the affected side is usually drawn toward the abdomen from irritation of the ship-cas muscle.

4 Pulse and respiration may be somewhat rapid but are generally only elevated on account of pain. In later stages, however, they too may react to the toxic absorption.

Any or all of these signs or symptoms may be absent. Their presence depends on the location and extent of the injury, and it should be remembered that too much dependence must not be placed on either their presence or their absence.

DIAGNOSIS

The diagnosis of ruptured ureter is usually not difficult and may frequently be made from the history and subsequent symptoms. In cases in which a pyeloureterogram was made at the time of cystoscopy the extravasation of the contrast medium is readily seen. Cystoscopy and ureteral catheterization should be

Fig. 10—Ruptured ureter following injection of 10 cc. of sodium iodide into acutely infected kidney and ureter

avoided in fresh ureteral injuries, because of the susceptibility of the injured urinary tract to infection.

The most important diagnostic evidence obtainable is from excretory urography. Not only does this make the diagnosis of ruptured ureter certain but it outlines the course of treatment. If the excreted urographic medium extravasates outside the ureter, one may be certain that urine is also passing out with it, and

urgical drainage of the ureter is indicated. Pain and local tenderness over the course of the ureter, lasting more than twenty-four hours after dilation of a stricture or any other intra-ureteral manipulation, should make one suspicious of a ruptured ureter.

TREATMENT

The most important factor in the prevention of a ruptured ureter lies in the careful, gentle art of

Fig 12—A extravasation of shodan from the ruptured left ureter following injection of 3 cc. B after the intravenous injection of neo-iopax showing no extravasation from the left ureteral rupture. Note the left renal calculus.

cystoscopic manipulation. The realization that one is dealing with pathologic, friable tissues should enhance one's respect for intra-ureteral manipulation. Sometimes the most conservative method of treating an impacted ureteral stone is by immediate surgical removal, thus avoiding prolonged trauma to a damaged ureter. Occasionally a ruptured ureter will result even with exercise of the utmost gentleness and care, but such an occurrence should be rare.

Fortunately, most injuries following treatment or investigation of the ureter result in the cracking or splitting of a pathologic ureter, requiring merely the usual palliative remedies: rest, hot baths, forced fluids, local heat to the painful region, alkalis and sedatives. The symptoms may last as long as two weeks, but the customary duration is less than a week. The treatment should be conservative and expectant, with constant watching of the pulse, pain, temperature and abdominal rigidity.

If the pain, tenderness and rigidity persist more than twenty-four hours, an intravenous urogram should be done. This is the most accurate method of determining the extent of the urinary extravasation. If the extravasation is progressive, as shown by the excretory urogram, surgical drainage should be instituted immediately. Sometimes urinary leakage may be small in amount but the tissue reaction less effective or the infecting organisms more virulent, and an abscess, phlegmon or even septicemia may ensue, thus transforming the case into a serious clinical problem.

There is no general surgical procedure applicable to all types of cases. However, when definite extravasation exists, primary surgical drainage is usually

indicated. In one of the reported cases suture of the fistulous opening in the ureter was attempted, but urine continued to drain from the wound until an indwelling ureteral catheter was inserted. No attempt at repair of the ureteral fistulas in the other cases was made. Indwelling ureteral catheters were found to be a distinct aid in healing the ureteral fistulas in three cases, not only by diverting the urinary stream but by splinting the ureter.

SUMMARY

1 The possibility of rupture of the ureter following manipulation must always be considered. It is more common than one would be led to believe.

2 Many such cases go undiagnosed and heal without surgical intervention. Severe postcystoscopic reactions may be the result of minute ureteral injuries with a small amount of urinary extravasation.

3 Surgical intervention is indicated when excretory urography shows extravasation.

4 Gentle and careful intra-ureteral manipulation, particularly in a pathologic ureter, should always be the aim of the urologist.

5 Nine cases of ruptured ureter, all following ureteral manipulation and injury, have been collected and are reported. Three required surgical drainage alone, two were subjected to nephrectomy because of badly infected kidneys, the remaining four recovered with palliative treatment.

6 Experimentally, it was found impossible to rupture the normal ureter of the dog by forcible dila-

Fig 16 (dog 1)—A the right ureter was dilated with a number 9 F bougie. This was withdrawn and a number 6 F catheter was inserted. Ten cubic centimeters of sodium iodide solution was forcibly injected showing a normal kidney pelvis and ureter with no rupture. A small silver wire with a sharp point was used to rupture the left ureter. Injection of 15 cc of sodium iodide through a ureteral catheter showed the ruptured ureter with extravasation. B neo-iopax the following day showed left kidney and upper ureter and extravasated neo-iopax at the point of rupture. This perforation was found at autopsy.

tion with a large bougie during cystoscopy. Retrograde pyelography with forced syringe injections, as well as excretory urography, showed the ureter still to be normal.

7 In three dogs the left ureters were forcibly ruptured and torn with a silver wire. Retrograde pyelography was then done to trace the extent of the extravasation. This was followed by excretory urograms and a similar extravasation occurred. In these ruptures surgical treatment was indicated because the excreted urographic fluid mixed with urine extravasated outside the urinary tract.

8 The ureter of one dog punctured by a fine wire stylet failed to show any extravasation of fluid by an intravenous urogram.

9 From a critical analysis of experimental and clinical data, excretion urography would seem to indicate accurately the existence and extent of gross injury or damage to the ureter. Also careful study and correct interpretation of the urograms are an invaluable guide to the further intelligent surgical conduct of the conditions arising from such injury.

901 Lexington Avenue

UROGRAPHY AS GUIDE TO SURGICAL INDICATIONS OF DIVERTICULA OF URINARY BLADDER

ROBERT H. HERBST, M.D.

CHICAGO

The history of diverticulum of the urinary bladder belongs to a very recent chapter of surgery in that the literature prior to the first years of this century contained little more than reports of the finding of these sacs in the dead house or their unexpected discovery at operation.

The diagnostic methods and the surgical correction of diverticula began their active development with the practical use of the cystoscope and the roentgenologic study of the urinary tract.

ETIOLOGY

In the early years the accepted etiologic factors were those of obstruction associated with weak areas in the bladder wall, and diverticula were classified as congenital or acquired, the differentiation being based on the presence of muscle fibers in the wall of the diverticulum. As diverticula are understood today, only a few, if any, are congenital, and some muscle fibers will be found in most of the walls of these pouches if examined carefully.

Although obstruction and congenital weak areas in the bladder have a decided influence on diverticulum formation, modern studies have uncovered other factors in this problem which have a bearing on their classification, clinical course and surgical indications.

Cystoscopic and roentgenologic studies have demonstrated that there is a marked difference in the orifices of these pouches, and the type of orifice has a definite bearing on the clinical course. The formation of the orifice is, to some degree, dependent on the changes that occur in the musculature of the wall of the bladder under various forms of prostatic obstruction. From a surgical standpoint they may be divided into wide neck nonretention and small neck retention diverticula.

In the average case of obstruction at the neck of the bladder due to hypertrophy of the prostate, distention of the bladder may develop in a comparatively short

period. Under these circumstances the bladder is dilated and the wall thinned out, and if a diverticulum forms it may be of the large neck nonretention variety.

In contrast to this, in the forms of obstruction such as fibrosis, median bar and less commonly hypertrophy, the distention may develop gradually. This permits the development of compensation on the part of the bladder wall, and when this process is completed the result is a small thick-walled contracted bladder in which the intracystic pressure is increased. Diverticula found under these conditions are usually the small neck retention type.

When infection is present in the bladder, the wall of which has thickened and contracted in its effort at compensation, more powerful contractions are stimulated, which in turn increases the intracystic pressure, resulting at times in the formation of small neck diverticula.

Much of the present-day knowledge of the important part played by the wall of the bladder and increased intracystic pressure in the production of diverticula is due to the work of D. K. Rose in his study of the physiology and mechanism of prostatic obstruction. In his paper on changes in the wall of the bladder secondary to prostatic obstruction he says:

Cases of prostatic obstruction may be divided into those in which the obstruction gains control early in the course of the disease and those in which the wall of the bladder (e.g., anatomic compensation) retains its ascendancy over the obstruction. In the second type the obstruction is imperfect and

Fig. 1—Cystogram of dog's bladder showing the development of a small thick-walled contracted bladder and small neck retention diverticulum produced by moderate obstruction at the bladder neck over a long period and later infection.

develops slowly and the wall of the bladder compensates readily on relief of the acute dilatation. It is in this type that diverticula frequently develop.

Some of the principles brought out by Rose were well verified in an animal experiment carried out by us some time ago (R. H. Herbst and Hugh J. Polkey). In this experiment we were attempting to produce diverticula in the dog's bladder for the purpose of determining the mode of development of large and small neck varieties. In this study we found that by plicating the neck of the bladder (in order to produce prostatic obstruction) a rapid dilatation of the bladder wall followed, and if diverticula developed they were usually

of the large neck nonretention type. We then changed our technique, producing a very moderate obstruction over a long period of time later infecting the bladder by injecting cultures of bacteria. This was followed by the formation of a small thick-walled contracted bladder, and when a diverticulum was formed it was the small neck retention type (fig 1).

This confirms the point made by Rose that the type of obstruction which produces a slow gradual disten-

compensation on the part of the bladder wall. Also, sufficient credit was not given to other stimuli, such as infection and foreign bodies. The irritation caused by these stimuli results in more powerful contractions of the bladder wall and adds to the already increased intracystic pressure.

SYMPTOMS

The clinical picture in small neck retention diverticula is usually quite different from that seen in the wide neck nonretention forms. In the former there may be a long history of mild urinary symptoms beginning in middle life or earlier. This is followed by marked frequency and increase in the force of the stream. An active form of incontinence is often present. The rectal examination reveals a normal, or only slightly enlarged, prostate, and the quantity of residual urine is small. The symptoms of renal damage are out of proportion to the amount of retention. These patients often exhibit the two stage type of urination.

In the less frequent large neck variety the symptoms appear later in life and are not as active. The rectal manifestations are those of hypertrophy, and the catheter usually recovers a large amount of residual urine.

DIAGNOSIS

The urographic study of bladder diverticula offers a means not only of visualizing these sacs but also of determining their number, size and shape, the presence of tumor or stone in the sac, their relation to the bladder wall and ureter, and the condition of the bladder wall itself, whether or not reflux has occurred, and if so, the degree of dilatation of the ureters and renal pelves (fig 2). Also, and of great import, the cystogram gives an accurate means of determining whether or not the diverticulum empties coincidentally with the bladder, in other words, whether one is dealing with a retention or a nonretention pouch, a point on which, in many cases, the question of surgical correction hinges.

Fig 2—Small contracted bladder with cellulose formation and large retention diverticulum pushing bladder to right side of pelvis. The obstruction at the bladder neck in this case was caused by fibrosis.

tion of the bladder gives the bladder wall an opportunity to compensate, resulting in a thick, hypertrophied wall.

The intracystic pressure in such bladders is increased, and when other stimuli such as infection or trauma are added to this picture the pressure may be sufficient to cause herniation of the bladder wall resulting in the formation of diverticula, and pouches formed under these conditions are often of the small neck retention type. This powerful contraction of the bladder wall and increased intracystic pressure often results in severe ureteral reflux and renal damage.

In contrast to this, in simple prostatic hypertrophy the obstruction and retention develop faster, resulting in a comparatively rapid dilatation and thinning out of the bladder wall. Under these circumstances there is not as much strain on the weak regions in the bladder, and diverticula when found, are usually of the large neck nonretention type. Here severe forms of ureteral reflux and renal damage are not as frequently seen, the renal changes being due to gradual back pressure rather than active reflux. If compensatory changes occur in these bladders, the orifice of the diverticulum narrows down and it becomes a retention diverticulum. This is probably a frequent occurrence.

As early as 1919, Hinman called attention to his statistics and those of others, which showed that diverticula were found more often associated with median bar obstruction than with simple hypertrophy of the prostate. He also expressed the belief that diverticula rarely if ever were congenital the type of obstruction and the conditions which cause increased intracystic pressure being the main exciting factors in the formation of these pouches.

Experimental failure of others to produce diverticula in the past, and also in our earlier work, was due to the fact that we did not recognize the effect of moderate obstruction over a long period of time which permits

Fig 3—Small triangular contracted bladder and two large retention diverticula. Urinary obstruction was caused by a fibrotic bladder neck.

The visualization of diverticula may be carried out by the direct injection of the bladder with a contrast fluid or by intravenous injection of one of the preparations used for this purpose. Each method has its advantages. The direct injection, if the pressure and amount injected are controlled, gives good visualization distinguishes between retention and nonretention types and demonstrates ureteral reflux, if present. Several views anteroposterior oblique and lateral should be made. The intravenous method offers a means of visu-

alization without the use of the catheter which is of definite value under certain circumstances. With this method it is not always possible to determine whether or not the diverticulum empties coincidentally with the bladder, and it may be necessary to use a catheter to obtain the correct information on this point.

The intravenous urogram is particularly valuable in making an early diagnosis in cases of moderate obstruc-

Fig 4—Same as figure 3 after catheterization. Diverticula did not empty coincidentally with bladder (retention type)

tion in which one wishes to avoid the use of the catheter. Here one may see the trabeculated bladder with beginning cellule formation. Trabeculation and cellules are the forerunners of diverticula, and the stimulus of infection and added intracystic pressure may complete the formation of such pouches. Therefore one should avoid, if possible, anything that might tend to increase the intracystic pressure until the obstruction at the bladder neck has been completely eliminated. In other words, when by means of a urogram a small contracted bladder with cellule formation is visualized, the prompt removal of the obstruction may prevent the formation of diverticula which may form from the added stimulus of infection.

Wide neck diverticula (small and even moderate size) which empty coincidentally with micturition do not require surgical intervention other than the elimination of the obstruction at the neck of the bladder. Practically all diverticula with narrow orifices fail to empty with the contraction of the wall of the bladder and must be removed before, at the time of or soon after the correction of the obstruction if one hopes to obtain a good functional result. Herein lies the value of the urographic study, which not only is helpful in making the diagnosis but also throws a definite light on the surgical indications.

In retention diverticula there is, without question, a predevelopmental period, a time during which there is a three-way battle between the obstruction at the bladder neck, the expulsive power of the bladder wall, and the action of the trigonal muscle. This is the time during which the bladder wall thickens and becomes trabeculated, and all that is needed to blow out the diverticulum and cause a severe ureteral reflux is some extra stimulus that will increase the intracystic pressure. I saw this in experiments on dogs and every physician has seen it happen clinically.

Transurethral removal of bladder neck obstruction offers a simple and accurate means of correcting the type of obstruction that is most frequently complicated by diverticula. If the diagnosis is made in the pre-

developmental period the patient may be saved a diverticulectomy.

I believe that small diverticula are best handled by inverting the sac into the bladder by suction, as described by Young, or drawing them in with forceps and excising them. For the large sacs I prefer to excise them by isolating the bladder and diverticulum completely without opening the bladder, then drawing off the contents of the bladder and diverticulum with suction, excising the diverticulum with its neck, closing the aperture and draining the bladder with a small tube through a small opening in the anterior wall. In this way the diverticulum can be removed without soiling the surrounding tissues, and the separation of the wall of the diverticulum, when distended, is simpler than when collapsed.

In cases in which the obstruction is due to fibrotic changes, it may be corrected by transurethral resection at the time of or shortly after the diverticulectomy. This approach offers an easy and accurate means of revising the bladder neck.

REPORT OF CASES

By way of illustration a few cases are cited which substantiate the foregoing discussion.

CASE 1—A man, aged about 56, had had mild urinary symptoms for about a year. Rather suddenly, about ten days before admission, these symptoms became acute. At times he was unable to urinate. On rectal examination the prostate gland was not enlarged. A large irregular mass could be palpated above the pubis. A study of the renal function showed a moderate degree of renal damage.

Cystoscopic examination disclosed a small contracted trabeculated bladder with two diverticular openings on the posterior wall, near the right ureteral orifice. Many small cellules were seen. A cystogram showed a very small bladder with an irregular border and two large retention diverticula extending to the right of the bladder (figs 3 and 4). Each of these pouches was three times the size of the bladder. The intravenous pyelogram revealed a bilateral hydronephrosis.

Fig 5—Small contracted bladder and retention diverticulum which developed after the closure of the suprapubic fistula. The obstructing prostate had been removed a few weeks previously.

This case illustrates the mechanism of the development of the small thick walled contracted bladder and retention diverticula resulting from a moderate obstruction due to fibrosis of the bladder neck.

CASE 2—A man aged 63, on admission to the hospital gave a history of prostatism over a period of two years. Hypertrophy of the prostate, grade 3 was found on examination,

with marked retention of urine and a moderate degree of renal damage. No diverticulum was found in the bladder. A two-stage prostatictomy was carried out. The day after the suprapubic wound closed a severe frequency and urgency developed with some elevation of temperature. The urine was frequently and forcefully expelled in small quantities, and the patient complained of severe pain during each micturition. The urine contained some blood and was crowded with pus. Bladder irrigations and an indwelling catheter failed to relieve his distress.

Fig 6—Small contracted bladder and retention diverticulum caused by a mild form of obstruction and a foreign body in the bladder

At the end of three weeks a cystogram showed a small contracted bladder and a retention diverticulum about the size of a small apple (fig 5)

What took place here was that immediately following the closure of the suprapubic wound the compensated bladder became infected and the powerful contractions caused a decided increase in the intracystic pressure, sufficient to blow out a diverticulum in a short time in spite of the fact that the obstruction at the neck of the bladder had been entirely removed. This case, as did also one of our dog experiments, demonstrates the importance of infection in the production of diverticula in the compensated bladder.

CASE 3—A man, about 30 years of age had had some frequency and difficulty of urination since childhood. He had a perineal section performed for the relief of this a few months prior to admission to the hospital. He stated that two weeks after this operation the urinary symptoms became exceedingly aggravated with severe frequency, urgency and strangury. He obtained no relief from bladder irrigations and sedatives. A cystoscopic examination on admission to the hospital revealed a small contracted bladder containing a large red rubber drainage tube (fig 6). An opening of a small neck diverticulum could be seen just above the left ureteral orifice.

The story in this case is quite clear. The patient evidently had had a moderate obstruction for which a perineal section had been performed. The drainage tube worked itself into the bladder and was overlooked by the surgeon. Its presence caused irritation and contraction in a compensated bladder, resulting in the formation of a diverticulum and the severe symptoms that followed the operation.

Stones or any foreign body in a contracted bladder may produce the same results.

CASE 4—A woman, aged 74, had had a mild form of frequency for years. During this time she had a number of short attacks of acute urinary symptoms. She noted that micturi-

tion had become increasingly more difficult and of late she had suffered from an active form of incontinence.

On vaginal examination, when the vulva was opened a moderate sized cystocele was noted. On cystoscopic examination the bladder was found contracted and showed a marked degree of trabeculation. There was a definite dipping down of the bladder in the region of the trigon, a condition frequently seen when a cystocele is present. An opening of a diverticulum was seen to the right of the right ureteral orifice.

In this case the change in contour of the neck of the bladder produced by the cystocele was sufficient to cause a mild obstruction. In an effort at compensation, the bladder wall thickened and the bladder contracted down and repeated infections caused sufficient increase in intracystic pressure to produce a retention diverticulum. The method by which the diverticulum was developed in this case is quite similar to that seen in male patients with prostatic obstruction, illustrating that even the mild obstruction produced by a cystocele is enough to cause the formation of a thick walled contracted bladder. Aided by infection, a diverticulum was formed (fig 6).

SUMMARY

1 From the standpoint of the surgical indications, diverticula of the urinary bladder should be classified into (a) small neck retention diverticula, and (b) large neck nonretention diverticula.

2 The retention types are found more commonly associated with fibrosis and bar formation at the bladder neck. The less common nonretention types are usually found associated with prostatic hypertrophy.

3 The mechanism in the development of each variety is quite different.

4 The powerful contractions of the small thick walled bladder stimulated by infection causes severe increased intracystic pressure, which may result in the formation of small orifice retention diverticula and serious renal damage from ureteral reflux. This mechanism is demonstrated both in animal experiments and in clinical cases.

5 The roentgenologic study is of great value both in diagnosis and as a guide to surgical indications.

6 Small and even moderate size nonretention diverticula do not require surgical attack other than the correction of the obstruction at the bladder neck.

7 Practically all retention diverticula must be removed if one may hope to obtain a good functional result.

8 Early correction of the milder forms of bladder neck obstruction such as fibrosis and median bar, may prevent formation of diverticula of the bladder and serious renal damage.

ABSTRACT OF DISCUSSION

ON TAINTS OF DRS. HENLINE AND HERBST

DR MILFA B. WESSON, San Francisco. Dr Herbst's report of a diverticulum that formed as a result of infection while the patient was convalescing from a prostatectomy is sufficient to cause one to make routine intravenous urography with lateral cystograms in all cases in which there are prolonged hospital stays. Dr Henline has made several points that I want to emphasize. 1. Normal ureters cannot be ruptured unless a wire stylet or whalebone tip is used and such an accident causes practically no symptoms and cannot be diagnosed without an immediate retrograde injection of the pyelographic medium. 2. Pathologic ureters can be performed by a stiff catheter or by an excessive pressure syringe pyelogram and the frequency of such accidents can be determined only by the routine use of intravenous urograms. 3. In no case of perforation of the ureter will there be an extravasation of urine unless there is an obstruction to the downward flow of urine. 4. A ureteral stone may macerate the wall until it becomes sieve-like and following an excessive syringe pressure attempt to make a pyelogram the sodium iodide may spray through the wall and cause local burning or the stone may be forced through the wall of the ureter with resultant perinephric abscess and occasionally eventual spontaneous drainage into the colon or groin. 5. Intervals between ureteral manipulations should be sufficiently great to permit the ureteral mucosa to return to normal. I recently saw in autopsy in a case in which catheterization had been done by a colleague twenty-four hours before at which all cystoscopic observations were negative. Two new No. 6 flute tip catheters were used and yet there were two angry looking red streaks extending the full length of each ureter. 6. Intravenous urograms should be made in all cases of cystoscopic manipulation for the removal of ureteral stone by indwelling catheters. If the catheters are plugged with toothpicks the urograms will usually be superior to those made by the retrograde method, in that the cortex and pelvis will both be outlined and the ureters stretched to capacity, so that a leak can be identified. Mere pyelitis does not indicate a weakened diseased ureter. I tried to perforate autopsy specimens from patients who had pus in the urine. I tied knots in the ureters and when I tried to tear through the wall, the catheters and bougies merely buckled in the bladder. Then I cut the bladder open and held the sides of the ureteral orifice with artery clamps and still the bougies buckled. With a No. 11 bougie I finally tore the ureter by grasping the instrument so close to the ureteral orifice that it could not buckle.

DR THOMAS D. MOORE, Memphis. Stricture of the urethra by causing a slowly developing obstruction may in turn cause diverticula of the small neck retention type. This emphasizes the necessity of a cystoscopic examination or a cystogram as a routine measure on completion of a series of urethral dilations, otherwise such diverticula may go unrecognized. For the same reason, preliminary cystography also should be employed as a routine in cases of prostatic obstruction. In order to assure clear definition of the sac the radiopaque medium should not be too concentrated. A 3 per cent solution of sodium iodide has proved to be of sufficient density is nonirritating and is inexpensive. In many cases the impaired renal function, so common with diverticula, contraindicates the use of excretory urography for cystograms. Lerche's method of introducing into the sac a small balloon on the end of a catheter has been found satisfactory. The diverticulum is thus converted into an enucleable tumor. If one is careful of the toilet of the bladder followed by adequate drainage of the extravascular area there should be no great fear of opening the bladder. Dr Henline has presented a timely discussion of the experimental, clinical and urographic aspects of rupture of the ureter. His observation that excretory urography can be used in such a dependable way in indicating the proper treatment is of inestimable value. Several years ago I had my first experience with a ruptured ureter which became evident about twenty-four hours after dilating the ureter with a wax bulb fixed near the tip of a Blasucci catheter. Excretory urography was unknown at that time. The clinical suspicion of a ruptured ureter was confirmed however by surgical exploration. There was urinary extravasation below the kidney. Although free

drainage was established the infection was very virulent several days later the kidney was removed because of multiple cortical abscesses. Following the nephrectomy the patient made a satisfactory convalescence. When a stone is tightly impacted in the lower part of the ureter, the relaxation obtained by a low spinal anesthesia is of great assistance in passing the obstruction, perforation or trauma of the ureter is less likely to occur. Any metal type of ureteral stone dislodger should be used with great care and only after the ureter has been dilated sufficiently to make possible its easy insertion.

DR WILLIAM E. STAVINS, San Francisco. As Dr Henline has stated accidental injuries of the ureters are more common than would be supposed from the infrequent reports in the literature. They occur occasionally during cystoscopic manipulations and are fairly common during operations on the female pelvic organs. These injuries are often overlooked because of the absence of symptoms in some cases. Three of the four cases of perforation of the ureter that have come under my observation healed spontaneously without marked symptoms. Dr Henline's interesting experimental work confirms the experience of Wesson proving that normal ureters cannot be perforated by ordinary ureteral catheters. It is possible, however to perforate the pelvis of the kidney. I have seen three cases in which it was perforated by catheters as far as the fibrous capsule. The necessity for care and gentleness during ureteral instrumentation as well as during pelvic surgery cannot be overemphasized.

DR O. S. LOWMEYER, New York. I congratulate the authors on their application of animal surgery to urologic problems. In spite of the fact that there is great danger in making pyelograms in addition to cystograms for diagnosis of vesical disturbances I do not know of any way of doing without them. The important point is to determine whether or not the diverticulum is a retentive one. If it is retentive, the cause must be eliminated as soon as possible but the retention must be overcome first. Lateral pictures are very important in determining the size of diverticula. To repair a diverticulum the bladder should be opened and the dissection carried down to the neck of the diverticulum. This opens things up so thoroughly that quicker and better operations can be done. Dr Herbst has pointed out the great value of resection of the vesical neck. I agree with that and wish to point out that diverticula are not rare in children and are usually due to some congenital obstruction that can be easily removed by resection of the vesical neck. Valves are diagnosed by the splendid endoscope Dr Campbell devised and in the older patients an instrument of mine is applicable. Dr Henline has worked up in an interesting way a subject I have tried to avoid. Early operation is desirable when one has made a diagnosis and it is realized that extravasation is going on and not being repaired by nature. These patients, unfortunately do not get very sick at first but later develop serious symptoms as the result of extravasated urine. If one does not make up one's mind quickly the patient gets so sick that operation is inadvisable since it is attended with shock, which may lead to a fatal issue.

DR ROBERT GUTIERREZ, New York. I was greatly interested in Dr Herbst's paper. We in New York are familiar with his research on dogs in regard to diverticula. I think that two points should be emphasized. First diagnosis must be accurate and the surgeon must know whether the diverticulum is of the retentive type. If it is, there is no question that sooner or later it will become a surgical entity. Second, in many of these cases of obstruction an endoscopic resection does not relieve the condition. These points have been well emphasized in Dr Herbst's paper. I have recently had two cases in which I have resected the bladder neck and one patient still has retention. In the study some years ago sixty-five cases were presented and the value of adding a third stage has been demonstrated first removing the obstruction at the bladder neck then doing a cystoscopy and then removing the diverticulum. When this is done the method is safe and the results obtained are always good.

DR J. S. EISENSTAEDT, Chicago. The work of Dr Herbst during the past six years has been accepted as a very important contribution to the subject of etiology of bladder diverticula. I have had experience with more than twenty diverticula which I have surgically removed. I believe that in most

of them inversion would have been impossible by any method of aspiration or suction. The majority have been so adherent to the surrounding tissues that it was only with difficulty that they could be freed in their entirety. In many instances I have found it necessary to open the bladder cavity itself and operate with one index finger within the diverticulum and the other hand outside the bladder. In others, in order to free the cupola of a long diverticulum it was found necessary to cut the wall of the diverticulum to within 1 or 1½ inches from the cupola. Fibrosis of the bladder neck should be emphasized as an important contributing cause of diverticula. The largest diverticulum in the series contained approximately 2 liters of urine and was at least ten times the size of the fibrotic contracted bladder. It was associated with marked fibrosis of the bladder neck. Drainage was established at the time of the diverticulectomy and later resection of the vesical neck was done. The patient regards himself now as entirely well. There is one type of bladder diverticulum which in my experience is very uncommon but of great importance as a cause of possible ascending renal infection. This type has a minute orifice which is likely to be missed at cystoscopic examination and which I am inclined to believe would not fill by cystographic methods. Such a diverticulum occurred in one of my cases and was situated at the bladder vertex. It was not visualized by cystoscopic examination and was not seen at the time the suprapubic cystostomy was done. The patient was permitted to retain his cystostomy tube for a long period, but his condition did not improve as I hoped it would and he died about fifteen weeks after the cystostomy. At necropsy a diverticulum as described was found, the orifice of which only admitted the smallest silver probe. The contents were purulent in character and undoubtedly served as the source of an ascending pyelonephritis.

DR P E McCOWAN, Indianapolis. I recently studied a case in which on first examination I saw marked prostatic hypertrophy. I made an intravenous pyelogram the following day and got astonishing information. The patient had renal stones, a small contracted bladder and a diverticulum that was much larger than the bladder.

DR ROBERT H HERBST, Chicago. I should like to utilize the time allowed for the closing discussion to show some lantern slides of my dog experiments and clinical cases which serve to illustrate the mechanism of the development of retention diverticula.

DR R B HENLINE, New York. Urologists who use either the Kelly cystoscope or the McCarthy panendoscope for dilating ureters must be particularly careful in using a steel stylet in a catheter or a firm bougie. Theoretically the stylet should be introduced just within the mouth of the ureter and kept at this position while the catheter is passed upward to the kidney. But frequently this detail is overlooked and the stylet is inserted with the catheter completely to the kidney pelvis. The wire stylet causes the catheter to be less flexible and hence one is more apt to rupture a pathologic ureter. Secondly, I believe that many postcystoscopic reactions are the result of the use of either too large catheters or bougies in diagnostic procedures or because of the lack of gentle manipulation. This has caused many physicians as well as patients to consider cystoscopy a horrible and painful procedure. It is my impression that most of these cystoscopic and postcystoscopic reactions can be avoided by the use of smaller ureteral catheters and more gentle manipulation during cystoscopy.

Symptoms of Coronary Infarct—Pain being the salient feature of coronary infarction we are apt to forget that it may be insignificant or entirely absent. In the absence of pain the outstanding clinical manifestations which indicate a coronary infarct are two—dyspnea and shock. The picture varies but the sudden and spontaneous onset of dyspnea either continuous or in paroxysms is suggestive—more particularly if it is not clearly benefited by rest. Again a sudden and inexplicable collapse with a drop in the blood pressure may be the first indication of the cardiac accident. "Waves of faintness" overwhelm the patient, his face is pale, ashen and moist with cold sweat—Hav. John. Certain Aspects of Coronary Thrombosis, *Lancet* 2 787 (Oct 7) 1933.

ATYPICAL FORMS OF DRY PLEURISY

A RADIOLOGIC AND CLINICAL STUDY

SAMUEL BROWN, M.D.

CINCINNATI

While it is true that the radiologic method has greatly improved diagnostic accuracy in pleuritic disorders, its chief function in most cases is that of confirmation of the clinical and physical observations. However, there are certain atypical forms of pleurisy namely the interlobar, the mediastinal, the paravertebral and the diaphragmatic which are seldom diagnosed by the physical and clinical signs alone but may be recognized by the radiologic method, provided the proper x-ray technic is used in the examination of the chest.

X-RAY TECHNIC IN THE STUDY OF THE PLEURA

The x-ray technic consists in the study of the chest in both the anteroposterior and the lateral position. These two positions will enable one to localize any abnormal

Fig 1—Diagrammatic representation of a cross section through the thorax (Cunningham Manual of Practical Anatomy). A parietal pleura B pleural cavity C visceral pleura

shadow in the lung field and thus to determine its exact relationship to the interlobar fissures, the mediastinal structures, the spine or the diaphragm. It will be evident, therefore, that a knowledge of the topography of the thoracic structures, as shown in the anteroposterior and lateral views of the chest, is absolutely essential for the correct interpretation of abnormal shadows due to pleuritic disorders.

ROENTGEN ANATOMY OF THE PLEURA

The roentgen anatomy of the thoracic structures including the pleura has been dealt with in detail in several previous publications.¹ For the purpose of completeness the most important facts will be briefly described in this paper.

In a cross section of the thorax (fig 1) it will be seen that the pleura consists of two closed sacs, one on each

Read before the Section on Radiology at the Eighty Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

side of the thorax, which envelop the lungs. The anterior margins of both sacs bend inward and backward, enclosing the heart, and are known as the mediastinal pleurae. The posterior margins of both sacs bend inward and forward enclosing the spine, and are known as the paravertebral pleurae. Above the apices of the lungs are covered by the apical pleura, which is a continuation between the mediastinal and

Fig 2 (case 1)—A Anteroposterior view showing a dense irregular shadow in the region of the right hilus. B Lateral view showing the dense shadow located between the upper and middle lobes anteriorly due to a dry pleurisy.

parietal pleurae. Below, the bases of the lungs are separated from the diaphragm by the diaphragmatic pleura. The most important point about the diaphragmatic pleura is that it is on a lower level posteriorly than anteriorly. Thus a lesion involving the posterior half of the diaphragmatic pleura may fail to be recognized if viewed only in the anteroposterior direction.

The interlobar pleura, which is formed from two visceral layers, occupies the lung fissures. Each lung is divided by an oblique fissure which corresponds to a line drawn from the second dorsal vertebra to the sixth rib in the mammary line. This fissure crosses the spine above, the roots of the lungs in the middle, and the heart below. The upper lobe of the right lung is subdivided by a horizontal fissure which corresponds to a line drawn from the center of the oblique fissure to the sternum on a level of the fourth costal cartilage. A very important point about the interlobar fissures is the fact that the horizontal fissure is the only one that is at right angles to the anterior wall of the chest, while the oblique fissures are at right angles to the lateral wall of the chest. It is for this reason that thickening of the interlobar pleura in the horizontal fissure is more readily recognized in the anteroposterior position of the chest, while thickening of the interlobar pleura of the oblique fissures is more readily recognized in the lateral position of the chest.

PATHOLOGIC CHANGES OF THE PLEURA

The pathologic processes that may involve the interlobar, mediastinal, paravertebral and diaphragmatic pleurae are the same as elsewhere in the pleura. The one chosen in this discussion is the dry fibrinous type. As a rule, the physician encounters no difficulty in the diagnosis of acute fibrinous pleurisy. The sudden appearance of a sharp pain in the side of the chest, which is aggravated by respiration and, when on physical examination a friction rub is felt or heard, the diagnosis of dry pleurisy is practically conclusive.

This is not the case with acute or subacute dry pleurisy involving the interlobar pleura, the mediastinal pleura, the paravertebral pleura or the diaphragmatic pleura. With the exception of diaphragmatic pleurisy, pain is seldom present. The most troublesome symptom is a dry cough, which is quite annoying at times. Although the patient is more or less indisposed, he seldom requires confinement to bed. The temperature is often found elevated from one to two or three degrees above normal. The pulse and respiration are seldom affected. The white blood cells may show a moderate increase in their number. Physical examination of the chest rarely reveals anything abnormal and, if it does, the conditions found are not distinctive of any pleuropulmonary disease with which the physician is familiar. A roentgen examination of the chest will invariably disclose an abnormal shadow in the lung field. When the exact location of the abnormal shadow is determined by means of the anteroposterior and lateral views of the chest, it will be found that the area involved corresponds to the region of the interlobar, mediastinal, paravertebral or diaphragmatic pleura and thus enables one to arrive at a correct diagnosis of dry pleurisy.

ROENTGEN CHARACTERISTICS OF DRY PLEURISY

The roentgen characteristics of dry fibrinous pleurisy depend on the region involved and the extent of the lesion. In the early cases one may find only a dense line corresponding in its position to the interlobar fissure, this is due to thickening of the visceral pleura. In more advanced cases one may find an elongated dense shadow that is more or less oval along the course of an interlobar fissure, this is due to a separation of the visceral pleurae as a result of an accumulation of a fibrinous exudate. Very frequently one may also find some involvement of the adjacent lung tissue. Abnormal shadows due to mediastinal or paravertebral pleurisy may show in the anterior view a dense shadow, which

Fig 3 (case 2)—A Anteroposterior view showing a dense shadow in the region of the middle lobe. B Lateral view showing a dense shadow located between the middle and lower lobes due to an interlobar pleurisy.

is usually narrow along the borders of the heart or spine. In the lateral position of the chest the abnormal shadow will be found to overlap the heart or spine, or both, depending on the extent of the area involved. In diaphragmatic pleurisy the diaphragm is found elevated and its outline is more or less irregular as a result of a fibrinous deposit.

REPORT OF CASES

Several cases have been chosen for a detailed description, illustrating the several atypical forms of dry fibrinous pleurisy.

CASE 1—A woman, aged 20, was referred for a roentgen examination of the chest because of a dry cough, slight elevation of temperature and more or less indisposition. At no time had she experienced any pain in the chest. Physical examination disclosed nothing abnormal. Stereoscopic examination of the chest in the anterior position (fig 2 *A*) revealed a dense shadow in the region of the right hilus. The exact nature of the abnormal shadow was not determined until the examination was also made in the lateral position (fig 2 *B*), which showed the abnormal shadow to be located anteriorly in the region of the horizontal fissure between the upper and middle lobes. From the size of the shadow and its outline one would judge that the adjacent lung tissue was also involved. About a week later a reexamination of the chest showed extension of the abnormal shadow along the horizontal fissure. Within several weeks the abnormal shadow gradually disappeared and with it the subjective symptoms.

CASE 2—A boy, aged 5 years, suffered an attack of whooping cough. Although the time for cessation of the symptoms was reached, the child continued to cough but without the whoop. There was a moderate elevation of temperature. The general condition of the child was good. Physical examination of the

Fig 4 (case 3)—*A* anteroposterior view showing a dense shadow on the left side of the spine superimposed on the heart. *B* lateral view showing the abnormal shadow overlapping the spine and heart due to a mediastinal pleurisy.

chest revealed nothing abnormal. A roentgen examination of the chest in the anteroposterior position (fig 3 *A*) showed an abnormal dense shadow in the region of the middle lobe. In the lateral position of the chest (fig 3 *B*) this shadow was found to be oval and located between the middle and lower lobes. The patient was reexamined several times and after five weeks the shadow was no longer seen.

CASE 3—A girl, aged 6 years, was admitted to the hospital because of a dry cough and a moderate elevation of temperature. Both the respiration and the pulse rate remained normal. Physical examination revealed abnormal changes at the base of the left lung posteriorly. The changes, however, were not distinctive of any definite pleuropulmonary lesion. The diagnosis of a pneumonia was suggested, but the absence of typical subjective symptoms with which pneumonia is generally associated made this diagnosis rather doubtful. A roentgen examination of the chest showed an abnormal dense shadow on the left side of the spine which was superimposed by the heart shadow (fig 4 *A*). In the lateral position the abnormal shadow was found to overlap the lower dorsal vertebrae and heart (fig 4 *B*). A diagnosis of mediastinal dry pleurisy was made. Within two weeks the abnormal shadow disappeared and with it the mild subjective symptoms.

CASE 4—A man, aged 29, presented symptoms consisting chiefly of a dry cough, slight elevation of temperature and a moderate indisposition. The respiration and the pulse rate remained practically normal. The white blood cells were slightly increased in number. Pain was absent. Physical

examination of the chest revealed a few abnormal changes that were not characteristic of any definite pleuropulmonary lesion. A roentgen examination revealed a dense shadow along the right border of the heart in the anterior position (fig 5 *A*). In the lateral position the lower dorsal vertebrae and heart were found more or less obscured by the abnormal shadow (fig 5 *B*). A diagnosis of mediastinal dry pleurisy was made. A reexamination of the chest was made two weeks later, and the abnormal shadow was no longer found.

Fig 5 (case 4)—*A* anteroposterior view showing a dense shadow along the right border of the heart. *B* lateral view showing the abnormal shadow overlapping the heart and lower part of the spine due to mediastinal dry pleurisy.

CASE 5—A woman, aged 50, was admitted to the hospital because of pain in the right side of the chest which was aggravated on deep respiration. There was a dry cough and a moderate elevation of temperature. Physical examination failed to confirm the clinical diagnosis of pneumonia and pleurisy. A roentgen examination of the chest showed an elevation of the right diaphragm, the outline of which was poorly defined (fig 6 *A*). In the lateral position the anterior half of the right diaphragm was found irregular in its contour, apparently because of a pleuritic exudate (fig 6 *B*). A diagnosis of diaphragmatic pleurisy was made. Within a week the symptoms subsided and reexamination of the chest revealed a well defined diaphragmatic contour.

Fig 6 (case 5)—*A* anteroposterior view showing elevation of the right diaphragm, the contour of which is irregular. *B* lateral view showing an irregular contour confined to the anterior half of the diaphragm due to diaphragmatic pleurisy.

COMMENT AND SUMMARY

The atypical forms of dry pleurisy are of frequent occurrence, but their diagnosis by means of the clinical and physical observations has been rather difficult. This is due to the fact that the symptoms and signs of the atypical dry pleurisies are not entirely the same as those

found in the ordinary dry pleurisies with which the average physician is fully familiar from the extensive medical literature. On the other hand the atypical forms of dry pleurisy have received but scant notice in medical literature. It is therefore not surprising that the diagnosis is seldom made in this condition. With the introduction of the x-rays and the examination of the chest in the anteroposterior and lateral positions, the diagnosis of atypical pleurisy has been made possible in a large number of cases. The study and correlation of the clinical physical and radiologic examinations have resulted in the recognition of certain symptoms and signs that are frequently associated with dry atypical pleurisies. These symptoms and signs are the following: moderate indisposition, dry cough, slight elevation of temperature, very little change in the respiratory and the pulse rate, moderate leukocytosis, no abnormal physical conditions (but, if present, they are not characteristic of any pleuropulmonary disease), with the exception of diaphragmatic pleurisy, there is no pain in the chest. Such observations should lead the physician to suspect the presence of an atypical dry pleurisy. The roentgen examination of the chest will very often confirm the clinical diagnosis of dry atypical pleurisy and thus relieve the physician and patient of the thought of the existence of something more serious than a simple dry pleurisy, the prognosis of which is generally very good.

707 Race Street

ABSTRACT OF DISCUSSION

DR. MOSES SALZER, Cincinnati. The development of the lateral view of the chest has definitely cleared up the diagnosis in many cases of obscure chest conditions. I cannot agree with Dr. Brown that all cases of this type are as mild in their symptomatology as in those reported by him in this paper. It is probable, however, that in many cases the acute symptoms had passed before he had an opportunity of seeing them. Many of these cases start out with a chill, high fever and a harassing cough, and one has the feeling that a pneumonia is developing. Contrary to Dr. Brown's statement, some of these patients do have pain in the chest. I feel quite certain that many of the cases which I formerly diagnosed as central pneumonias were cases of interlobar pleurisy. With the simple anteroposterior view, what appeared to be an area of consolidation was seen in many of these cases, and it was only after Dr. Brown developed the lateral view that I realized that probably many if not all of these were cases of interlobar pleurisy. An accurate diagnosis of these cases is absolutely impossible without the technic as outlined by Dr. Brown as in most of the cases I have seen there has been an entire absence of physical signs. Dr. Brown has called attention to the difference in symptomatology between diaphragmatic pleurisy and the interlobar type. In the former the pain is usually more pronounced. It is frequently abdominal. This difference in pain may be due to the fact that there is relatively little movement between the lobes of the lung. This may be an explanation also of the rarity with which fluid is encountered in interlobar pleurisy. The layers are joined by an adhesive pleuritis before fluid can form. The nontuberculous origin may also be a reason for the absence of fluid formation. It is remarkable how completely and how quickly all roentgenographic evidence will disappear after the patient's clinical recovery. This recovery is additional evidence that these cases are nontuberculous.

DR. LEON T. LEWIS, New York. A number of years ago in examining lung abscess cases I made use of the lateral view. Since that time I have made it a routine to have a lateral view in the examination of children at Willard Parker Hospital where there are many cases of pleuritic lesions associated with infectious disease. In that way a number of cases of interlobar pleurisy have been found at a very early stage that were not suspected on clinical examination and could not be made out on the posterior or anterior views. I agree thoroughly that a

lateral view should not be omitted. Roentgenologic chest examinations should not be considered complete without the lateral view.

DR. JOHN W. PIERSON, Baltimore. The anatomic structure of the lungs is such that it is extremely difficult to differentiate between pneumonic consolidations and interlobar pleurisies when the patient is examined in the ordinary position. The secret of the detection of interlobar pleurisies is to direct the x-rays perpendicular to the lung fissures. In order to accomplish that purpose, I have examined the patient in the lateral and semi-lateral positions which serve to demonstrate interlobar pleurisies between the upper and middle lobes on the right side and the middle and lower lobes on the left. The investigation of the fissures between the middle and lower lobes on the right side is best accomplished by placing the patient in the "kneel hold Stellung." The shoulders are placed against the film so that the body forms an angle of 20 degrees with the plane of the film, the rays being projected in the usual manner. The angulation of the patient's body with the film allows the rays to be projected upward through the thorax.

DR. LEO G. RIGER, Minneapolis. I have demonstrated in many instances in which an extremely small effusion was present, so small that it could hardly be detected as a shadow on the film that changing the position of the patient would produce a shadow suggestive of interlobar pleurisy which was not present in the other position. The same holds true of mediastinal pleurisy. I have recently seen a number of cases in which a very striking picture was presented of a large shadow projecting to the right of the midline resembling some what an enormously dilated right atrium. When examined in a different position it was revealed that the shadow was entirely due to free fluid which, in the new position, extended into the peripheral pleura. It was simply a matter of distribution of the fluid in the pleural space. One other point to which I would call attention is concerned with an error in interpretation of the lateral view in certain cases. Even in the cases in which the right diaphragm is not especially high, if lateral views are taken with the patient lying on one side the diaphragm may rise into this position so that a very dense shadow is produced. This can simulate the shadow of an interlobar effusion. The same phenomenon may occur also in those cases in which the right diaphragm is raised by a pleuritic effusion.

DR. SAMUEL BROWN, Cincinnati. The method of visualizing interlobar pleurisies as described by Dr. Pierson is familiar to me, but I do not think that it is as simple as the one I described. In determining the line of fracture in a bone one would take roentgenograms in the anteroposterior and lateral positions. Why not apply the same principle in the case of interlobar pleuritic disorders? Examination of the chest in the anteroposterior and lateral positions will seldom fail in demonstrating abnormal changes in the region of the interlobar fissures.

Acidosis—The discovery that monoiodoacetic acid has the power to prevent the formation of lactic acid in the living body makes possible a crucial experiment as to the real nature of the state now called acidosis. This state is now generally regarded as an acid intoxication. It is believed to be essentially similar to that induced experimentally by the ingestion or intravenous injection of hydrochloric acid. Acids are supposed to be liberated in the body under oxygen deficiency from any cause: intense muscular exertion, exposure to great altitudes, carbon monoxide fever especially in children, alcoholic intoxication, ether anesthesia, physical injuries and crushing of tissues, deficiency of insulin, as well as by an unbalanced diet. The symptoms in all such cases are now commonly assigned in large part to acidosis in the sense of acid intoxication. The acid most readily produced in the body is lactic acid. If then lactic acid is not a cause of acid intoxication it is doubtful whether any acid produced in the body can intoxicate. All such acids would then have to be regarded as mere accessories of the conditions they are now supposed to induce. The conditions called acidosis would not be acid intoxication. The outstanding phenomena of acidosis are the decrease of the bicarbonates of the blood and the increase of breathing.—Henderson, Yandell and Greenberg. *L. A. Acidosis. TRAUMATIC EPITHELIAL CYSTS OF
THE SKINMAX S WIEN, MD
AND
MARCUS R CARO, MD
CHICAGO

In 1855, Wernher¹ reported the excision of a nut-sized cystic tumor from the palm of a thresher. Mouron² later described cystic tumors occurring on the fingers of working people. These have since been reported under various names and have been described as subcutaneous hard, round, cystic tumors of varying size, occurring most often on the palmar surface of the hands and fingers and occasionally on the feet, and usually resulting from injury. The name "traumatic epithelial cysts of the skin" aptly expresses the traumatic etiology, the cutaneous site and the cystic nature of the tumors. The condition has also been known as "kystes epidermiques des doigts" (Reverdin³), "kystes dermoïdes" (Rizet⁴), "traumatic epithelial cysts" (Garre⁵), "epidermoïde" (Franke⁶), "atheroma" (Schweninger⁷), "traumatic epidermic cysts" (Unna⁸ and Darier⁹), "implantation cysts" (Sutton¹⁰), "traumatic epidermoid" (Blond¹¹), "implantation dermoid" (Burrows¹²) and "epithelial cysts of traumatic origin" (McCarthy¹³).

In spite of the antiquity of the disease and its apparently frequent occurrence, as evidenced by several recent reports in the foreign literature, traumatic epithelial cysts of the skin have been given but little notice in the American literature. We are reporting three cases, with histologic examinations of two.

REPORT OF CASES

CASE 1—M B, a white man, aged 47, a motorman was first seen on Jan 10, 1931. Twelve years previously he had sustained a deep cut on the volar surface of the first phalanx of the left middle finger. Owing to repeated pressure and friction against the motor handle used in his work the wound remained open for a long time. After healing occurred, the area became slightly elevated and firm. Subjective sensations were absent. About one month prior to his examination the same area was accidentally struck with a hammer. A soft swelling resulted that was tender to pressure. Two weeks later the scar of the original wound opened and a thick sticky substance was discharged. On examination the site of the wound presented a dime sized firm callus, covering a subcutaneous elevation.

Removal of this lid exposed a rounded tumor of rubbery consistency, covered by a smooth dark red surface. After incision there was expressed a small amount of thick, brownish mucoid substance. The tumor was easily removed by blunt dissection, and healing was rapid with no recurrence.

Histologic Examination—Hemalum-Eosin Stain. The tumor was cystic. The wall was composed of two layers, an outer cellular epidermis and a much thicker inner horny layer. There was no connective tissue capsule, and the outer boundary of the wall consisted of a single layer of columnar basal cells. Extending inward from this was a layer of varying thickness composed of polygonal prickly cells joined by distinct prickles. The granular layer was nearly continuous and varied from one to five cells in thickness. In one area the stratum lucidum was distinct, while elsewhere the granular cells bordered directly on the horny layer. In this the nuclei were absent throughout, the cell outlines were still visible only in the outermost layers, and there was a lamellated structure up to the very lumen. The lumen was small and contained a slight amount of debris (fig 1).

Sudan III Stain. A slight amount of fat was present in the horny layer.

Fig 1 (case 1)—Wall of the cyst composed of an outer stratified epithelium and a thick inner horny layer.

CASE 2—A physician, aged 34, was first seen on May 22, 1930. Calluses had been present on his feet for the past five years. In the past year he had noted an elevation on the dorsum of his left foot on the tarsal portion just behind his fifth toe. Pain on pressure was noted over the site during the past year. He did not remember any actual injury to this site, although pressure from his shoe had been constant. Examination revealed a fine verrucous surface overlying a small marble-sized rounded tumor of rubbery consistency that had a pearly appearance when the overlying skin was stretched. The lesion appeared to be cystic. It was removed under local anesthesia with the actual cautery. The lesion ruptured during its removal and discharged a grayish cheesy substance that physically resembled sebaceous material. Healing was rapid with no recurrence. Histologic studies were not made because of the destruction of the lesion during the course of its removal.

CASE 3—A housewife, aged 45, was first seen on Feb 26, 1930. For the past year she had had a small round tumor on the palmar aspect of the middle phalanx of the left middle finger. She did not remember any injury to the site but admitted occasional injury to the fingers in the course of her housework. There was no subjective sensation until three

days before examination, when slight pain over the involved area was noted. Examination revealed a cherry-sized round tumor at the site described. This was removed under local anesthesia with the actual cautery. Healing was rapid with no recurrence. The contents of the tumor physically resembled sebaceous material, similar to that described in case 2.

The diagnosis in this case was made by Dr. Richard H. Jaffe, who did the histologic studies in the work of Blond.¹¹

Histologic Examination—Hemalum-Eosin Stain. There was a cystic cavity filled with cellular debris. Surrounding this was a thick layer composed largely of densely packed foreign body type giant cells and large, pale, polygonal cells. In most parts this layer was demarcated from the lumen, but occasionally the giant cells extended irregularly into the debris. Scattered throughout the cellular layer were a few polymorphonuclear cells and many lymphocytes, the latter being especially dense at the periphery. Here there was a gradual transition to the dense fibrous capsule that surrounded the entire cyst. The blood vessels in the capsule were surrounded by thin mantles of lymphocytic infiltration. A smaller similar cyst was noticed

Fig. 2 (case 3)—Cyst filled with debris lined by a cellular layer rich in foreign body giant cells and covered by a dense fibrous capsule.

adjacent to the other cyst and separated by a dense fibrous wall (fig. 2).

Sudan III Stain. A considerable amount of fat was present in the cellular lining layer and in the contents of the lumen.

ETIOLOGY AND PATHOLOGY

While the traumatic origin of these cysts seems to be accepted by all observers, a history of injury is not always obtainable. Worz,¹⁴ in a review of the literature, found a definite history of injury in only twenty-four of fifty-five cases. Pietzner¹⁵ collected the reports of seventy-three cases from the literature and found injury noted as the cause in forty-three. The incidence of trauma, however, is undoubtedly higher than is apparent from these statistics. The injury may be slight enough to escape notice, and may have occurred months or years prior to the development of the cyst. Unna,⁸ and Ewing,¹⁶ mentioned the predilection of the cysts for sites that are frequently injured, such as the

fingers and palms and the high incidence among working people, while McCarthy¹³ occasionally found evidence of trauma in the form of a scar near the cyst. In many of the cases the injury is produced by a blunt or tearing instrument.

Briggs¹⁷ reported two cases of cysts of the fingers, one an encysted hematoma and the other an epidermoid cyst. Hartley's¹⁸ case was an intracranial cystic tumor which developed following a compound fracture of the skull. During the injury a bit of epithelium was implanted beneath the skull and developed into a cyst, which displaced the brain adjacent to it and also extended outward beneath the skin. Buerger¹⁹ gave a historical review and reported three cases of epithelial cysts. Two occurred on the fingers following puncture wounds by a needle and the third was present on the breast. Blond¹¹ reported six cases of cysts of the palms and fingers, in which injury was remembered in three. Burrows¹² reported a case in which a cyst developed on a finger at the site of a perforating injury by a piece of wire. Hammann²⁰ reported a case in which a cyst developed following an injury to the finger-nail. Behrens²¹ reported three cases, two of them definitely resulting from trauma, and gave an extensive review of the literature.

Several explanations have been offered for the method by which an injury may produce an epithelial cyst and for the source of the lining epithelium. These conceptions have been developed on the basis of experimental work and have been the source of much controversy.

Franke⁷ believed that the origin lay in embryonic epithelial cell rests. These were stimulated by trauma to produce epithelial pearls, which later became cystic.

Reverdin³ was of the opinion that in the course of an injury bits of epidermis were torn off and deposited deeply in the corium, and that cysts developed from these implanted grafts. Garre⁴ in elaborating this, stated that implantation of epidermis alone produced smooth-walled cysts, while in those resulting from the implantation of the entire skin, papillae were also present.

This conception was supported by the experimental work of Kauffman²² and Schweninger.⁵ The former produced cysts beneath the skin of the cocks comb. He made a complete oval incision deeply through the skin, allowing the central separated part to retain its continuity with the base. He then pressed the central piece down below the surface and sutured the edges of the wound together above it. The buried epidermis gradually took on a rounded form and invariably developed into a cyst. The origin of these cysts from the epidermis was evident, for the cocks-comb contains no hair follicles or glandular epithelium to provide another possible source. Schweninger repeated this experiment in dogs and was also able to produce subcutaneous cysts by burying pieces of skin below the surface. The cysts at times contained hairs and sebaceous glands in the wall, and fat, cholesterol and epidermal scales within the lumen.

Another possible origin was suggested by Pels-Leusden²³ and was supported by experiments performed on rabbit ears. He made incisions through the skin, using a sharp knife to prevent the accidental implantation of epidermis during the operation. He then placed absorbible magnesium disks deeply within the corium. About these foreign bodies, cysts were produced the lining membrane of which contained all the layers of normal epidermis. Pels-Leusden believed that the cysts were formed by proliferation from the epithelium of glands that were unavoidably injured. He thought it unlikely that in ordinary injuries the tough skin of the palms could be torn off and implanted.

Hesse²⁴ in a comprehensive series of experiments, buried magnesium disks cutgut and blood clots beneath the skin and later examined histologic serial sections of the sites of implantation. He demonstrated that epithelialization to produce cysts may take place from the hair follicles and glandular epithelium without any apparent burr of epidermis. He was unable to find papillae in the wall of any of these cysts, however, and he stated that for the development of papillae there was necessary an implantation of complete epidermis.

More recently Zimches²⁵ performed a series of experiments on dogs in which pieces of skin and adjacent corium were transplanted into various regions of deeper tissues in the same animal. Cysts composed of keratinized epithelium and hairs were produced. He stated that the tendency of transplanted surface epithelium to form cystic cavities follows a law which governs the growth of epithelium in general, namely, that the more active growth is always directed toward the nearest margin of epithelium. Garre in an earlier article, explained this process diagrammatically by showing that the displaced epithelium continues to grow in area and in thickness. Since considerable resistance is encountered on all sides it is forced to curl up and finally to become converted into a complete sphere. The cyst continues to grow because the lining epithelium constantly produces a cornified layer which is poured into the lumen.

The occurrence of foreign body giant cells in the lining of epidermal cysts has been explained by Stewart²⁶. According to him, the contents of a cyst, whether they are hair, fat, cholesterol or epidermal scales, have the irritant properties of a foreign body. In those parts of the cyst where the epithelial lining is lacking this irritation produces a type of granulation tissue that is rich in giant cells. White²⁷ was able to produce cystic foreign body granulomas in various animals by subcutaneous injections of saline emulsions of oleic and palmitic acids and oleic acid itself. An abscess cavity was formed which was lined by a densely packed layer of polygonal cells and foreign body giant cells. Burgess²⁸ observed the formation of similar granulomas about subcutaneously placed masses of calcium phosphate, calcium carbonate and cholesterol, as well as stearic and palmitic acids.

From the foregoing review it is apparent that the implantation of a foreign body in the skin may give

rise to a cystic lesion which is lined by granulation tissue rich in giant cells instead of epithelium. The foreign body may be preserved in the lumen, or it may be absorbed and not be present at the time of the histologic examination.

DIFFERENTIAL DIAGNOSIS

Traumatic epithelial cysts of the skin are not rare, and when seen may be easily mistaken for lesions of similar appearance occurring principally on the hands.

Synovial lesions of the skin occur over the joints of the fingers, usually on the dorsal surface, communicate with the underlying synovial bursa and contain yellowish viscous fluid. Fibromas are solid tumors of varying consistency that show abrupt elevation above the surface and are composed of fibrous tissue. Xanthomas are yellowish solid tumors which are embedded in the skin and which have a characteristic histologic structure. Ganglions occur most often on the dorsum of the hands, are larger, and are usually in connection with a tendon or joint. Their contents are usually a thick, glairy fluid. Sebaceous cysts may be confusing because of the gross resemblance. These, however, do not occur on the palms and fingers, since sebaceous glands are normally absent from these areas. Dermoids are congenital cystic tumors which occur most often on other parts and which contain hairs and occasionally teeth within the lumen. Juxta-articular nodes must also be differentiated.

SUMMARY

1 Attention is directed to traumatic epithelial cysts of the skin which have been previously reported under various titles.

2 These cysts occur on sites exposed to trauma and usually result from injury with blunt or tearing instruments.

3 Three cases are reported with histologic examination in two. These cases presented the clinical picture of traumatic epithelial cysts. Case 3 proved, on histologic study, to be a cystic foreign body granuloma.

4 The theories of their genesis are reviewed and include (a) formation from embryonic rests (Fianke⁶), (b) implantation of epidermis (Reverdin,⁴ Garre⁵), (c) origin from hair follicles and glandular epithelium (Pels-Leusden²³), and (d) cyst formation resulting from foreign body granulomas (White,²⁷ Burgess²⁸).

5 Several recent reports in the foreign literature indicate that these cysts are of rather frequent occurrence.

CONCLUSIONS

Traumatic epithelial cysts develop as a result of injury to the skin, usually produced by a blunt or tearing instrument. Such cysts occur most often on exposed sites, such as the fingers and palms and are especially prevalent in those occupations which predispose to injury.

The origin of the cyst is most probably from a bit of epidermis which has been torn from the surface and implanted in the corium. It may also originate from deeper epithelial structures in the absence of surface injury. Here the cyst may form about a foreign body by proliferation of epithelium from the hair follicles or the glandular structures of the skin. Occasionally a foreign body granuloma with cyst formation may simulate an epithelial cyst of traumatic origin.

ABSTRACT OF DISCUSSION

DR. WALTER J. HICHMAN, New York: This subject is timely and concerns a condition that would probably be found more frequently if it were watched for. It is in the study of skin tumors that there is a great practical field for the microscope. It is difficult to make the diagnosis with the naked eye. It is interesting that an integument that is subject to trauma of either the tearing or the contusing type can lead to the formation of lesions of this sort. I do not think, however, as was brought out by the authors that these lesions are necessarily epidermal in nature. Some are but others are traumatic lesions which originally took the form of semisolid infiltrations, which ultimately liquefied, becoming cystic. They are secondarily cystic. This differentiation does not need to be indicated in the nomenclature—it is sufficient if one suspects that the skin has been altered pathologically to find out what the change is by whatever means are at one's disposal in this instance the microscope. I do not know how to classify the implantation cyst that proves on further examination to be a cyst of some other origin.

DR. M. J. STRAUSS, New Haven, Conn.: In connection with the three cases presented I wish to place on record a similar case, which differs in two respects: first in the length of time between the injury to the appearance of the cyst and second in the contents of the cyst. The patient was a young girl who was stabbed by some sharp instrument over the insertion of the deltoid muscle and three months later developed a cyst at the site of the injury. The cyst was removed and on section showed in the midst of some degenerated caseous material small masses of squamous epithelial cells similar in appearance to surface epithelium, with nowhere any suggestion of the presence of a basal cell layer.

DR. WILLIAM A. ROSENBERG, Chicago: I was interested particularly in a slide in the second case for it presented numerous giant cells, and I understood the authors to say that there was an infiltration associated with that lesion. Aschoff in 1904 described nodules occurring in the heart in rheumatic patients, particularly in arthritis, which display typical manifestations and are known as Aschoff bodies. These lesions are not infrequent on the palmar surfaces of the fingers and have been demonstrated on various parts of the skin. I have recently seen a similar case at Northwestern University Medical School and wish to know whether in case 2 there were any symptoms of arthritis or evidences of a heart lesion.

DR. MARCUS R. CARO, Chicago: In a given case of a traumatic epithelial cyst of the skin it is difficult to determine the manner in which the cyst was formed. It has been proved in experimental work that any one of several ways may operate to produce such cysts. In some cases there is a direct implantation of a bit of skin during an injury. If epidermis alone is implanted a smooth cyst results, while for the production of papillae or accessory structures the whole thickness of skin must be buried. In other cases there is injury by a foreign body which traumatizes sweat glands, sebaceous glands or hair follicles. Epithelium proliferates at the point of injury and grows to cover the implanted substance. Finally, a not infrequent occurrence is an injury which elicits the production of a foreign body granuloma, which in turn becomes transformed into an epithelial cyst. White demonstrated this form of cyst formation by subcutaneous injections of irritants in experimental animals. About the injected irritant an abscess was invariably formed. At first this consisted of polymorphonuclear leukocytes. These became disintegrated to form a cavity containing necrotic debris. About this cavity a wall of histiocytes developed and eventually granulation tissue containing histiocytes and giant cells. If the abscess did not come in contact with epithelium, it remained unchanged. If, however, a hair follicle, gland or epidermis became exposed in the abscess cavity, the epithelium grew rapidly over the surface in all directions from the points of contact to form a lining of squamous epithelium. Any number of follicles or glands could take part in providing the lining for a single cavity. The case reported by Dr. Strauss was probably produced in this manner. The epithelialization of these cysts is explained by the natural tendency of epithelium to grow over any free surface. The process is very rapid and in some of the experiments the cysts

were produced and completely lined by squamous epithelium in less than two weeks. For the formation of such cysts the foreign body must remain intact long enough to produce a granulomatous reaction. It may be absorbed later, however, and may be absent at the time of examination. In reply to Dr. Rosenberg, I may state that our patient did not suffer from rheumatism or endocarditis and neither clinically nor histologically was there any resemblance to Aschoff bodies.

OVARIAN THERAPY

RELATIONSHIP OF THE FEMALE SEX HORMONE TO HEMOPHILIA

JACOB BREM, M.D.

AND

JEROME S. LEOPOLD, M.D.

NEW YORK

Since Birch's¹ announcement of the treatment of hemophilia with ovarian extract, several papers by herself and others² reporting beneficial results from the administration of this hormone have appeared in the literature. However, the conclusions arrived at have not been very convincing. The improvement was chiefly clinical and in most instances not substantiated by definite laboratory data. It is difficult to determine whether the hormone had a specific effect in bringing about the clinical improvement.

Moreover, Birch^{2a} attempted to correlate hemophilia with the female sex hormone. Assuming that the normal male is not pure male but part female, Birch demonstrated that the female sex hormone or estrogenic substance was present in the urine of normal males and absent from the urine of five hemophilic patients. Based on those results it is assumed that the symptoms of hemophilia are held in abeyance by the female sex hormone.

Because of the great significance of Birch's report, it was felt that her work should be repeated. An opportunity to study a hemophilic patient for a period of about six months presented itself. During this time, certain definite information was obtained which is worthy of publication.

The problem was approached from three different angles:

1. Parenteral injections of whole ovarian extract and ovarian follicular hormone were given to the hemophilic patient and the effect on his general condition was noted. Coincidentally, the coagulation time of the blood was determined at regular intervals to check the clinical course.

2. The urines of two hemophilic patients and normal male controls were assayed for the presence of the female sex hormone or estrogenic substance to determine the relationship of the female sex hormone to hemophilia.

3. After the parenteral injection of the ovarian follicular hormone an attempt was made to recover it from the urine of one hemophilic patient.

From the Abraham Jacobi Division for Children, Service of Dr. Jerome S. Leopold and the Achelis Laboratory of the Lenox Hill Hospital.

Before presenting our data, it would be well to give some pertinent facts concerning the case studied.

B. B., a white boy, aged 9½ years, entered the Lenox Hill Hospital, Dec. 18, 1932, for the sixth time. Since his first admission at 6 months of age, the patient had been known to bleed easily. He had been subject to numerous subcutaneous hemorrhages and hemarthrosis, involving various joints. There was a definite familial history of hemophilia. His brother, aged 10½ years, was also hemophilic.

On admission the patient had a recent effusion in the left knee joint, bilateral contractures of both knee joints, and a contracture of the right elbow. The bleeding time was two minutes and thirty seconds. The platelets numbered 330,000. The coagulation time of the blood was eighty-five minutes.⁴

Soon after admission 5 grains (0.3 Gm.) of whole ovarian extract (Hynson, Westcott & Dunning) was given intramuscularly daily. The effect of this prepa-

An attempt was then made to prove the relationship of the female sex hormone to hemophilia by assaying the urines of (1) normal adult males, (2) our patient and his hemophilic brother, and (3) normal controls of the same age group as our patient. For these experiments twelve female rats, each about 2 months of age, were secured. Daily vaginal smears were taken for a period of three weeks and examined by the Allen-Doisy⁶ method to determine whether the rats normally went into estrus. One of these rats did not show estrual changes during this period, presumably because of a vaginitis, and so was discarded.

A bilateral salpingo-oophorectomy was then done on the remainder of the rats through a dorsal incision as described by Durrant.⁷ About a week's time was allowed for the rats to recover. They were observed further for a period of three weeks to ascertain that the estrual cycle had ceased. One of the rats did show estrual changes at the end of the third week of observation. It was concluded that not all the ovarian tissue had been removed from this animal and it was discarded.

For the biologic assay of the presence of the estrogenic substance in the urine the method of Kurzrok and Ratner⁸ was employed. To make the test more sensitive, our maximum dose of the oily concentrate at each injection was 1 cc. instead of 0.5 cc.⁹ The urines of the patient studied, his 10½ year old hemophilic brother, two normal boys of the same age group as the patient, and two normal men, aged 24 and 29, were assayed. The estrogenic substance could not be found in the urines of the hemophilic brothers, but neither was it present in the urine of any of the normal male controls.

The presence of the estrogenic substance has been reported in the urine of males by Dohrn¹⁰ and others.¹¹ However, Frank,¹² in a series of twelve urines obtained from normal males was not able to find a single positive result when the concentrates were injected into mice. Freeman,¹³ was not able to find the estrogenic substance in male urine before puberty and only in one case after puberty—a youth, aged 18, with Frohlich's syndrome.

To theorize as to why certain male urines have estrogenic properties would not be of great value. Cook, Dodds and Hewett¹⁴ have found that the extracts, peat, lignite, coal tar, petroleum and sterol compounds have estrogenic properties. This observation may in some way account for the occasional presence of the estrogenic substance in male urine.

An attempt was then made to inject larger doses of the ovarian follicular hormone into our hemophilic patient to determine its effect on the coagulation time and to recover it, if possible, from the urine. Before this procedure was carried out, the method of extrac-

TABLE 1—The Effect of Parenteral Ovarian Therapy on the Coagulation Time of the Blood in Hemophilia

	Date	Coagulation Time
Whole ovarian extract started	12/23/32	
	12/24/32	75 minutes
	12/25/32	85 minutes
	12/26/32	100 minutes

TABLE 2—Normal Fluctuations of the Coagulation Time in Hemophilia

Date	Coagulation Time
3/21/33	68 minutes
3/30/33	55 minutes
5/13/33	43 minutes
5/14/33	72 minutes

tion on the coagulation time of the blood may be seen in table 1. Although the figures in table 1 point toward a reduction of the coagulation time of the blood it was clearly evident that the patient was not benefited by the administration of the hormones. Oozing from the nasal septum was present together with hemorrhage into the right biceps muscle.

Moreover, it was found (table 2) that the coagulation time of the blood fluctuated considerably in hemophilia. After the hormones had been discontinued for about three and one-half months the coagulation time was forty-three minutes, a figure lower than the lowest obtained with administration of the hormones. These results are in agreement with those of Blalock.⁵ He found that after the daily subcutaneous injection of an ovarian preparation in a hemophilic patient for a week the clotting time was two hours and five minutes. Before the injections were begun, the clotting time had been one hour and forty-five minutes.

⁴ The coagulation time was determined on venous blood. Two test tubes were used for each determination. If the blood in one tube coagulated first the average of the two determinations was taken.
